The various antenna elements **70–84** and insulators **86** may comprise a rigid frame forming the basic structure for the craft and inside of which the collecting grid **14** is supported and upon which the discharge electrodes **12** are mounted. The antenna elements **70–84** may be stacked vertically if desired to improve both the efficiency of the antenna and the rigidity of the basic structure. To the extent that the antenna elements may be galvanically connected together without interfering with the operation of the antenna in its conventional manner, the antenna elements are preferably connected to the same D.C. potential as collecting grid **14**. Thus, the antenna elements may also augment the operation of the Ionocraft by neutralizing charged ions which provide the propelling force.

In the rectangular embodiment of FIGURE 12, the several antenna dipoles **90** have different lengths so as to be equal to one half the wave length λ of the frequency being transmitted for an entire spectrum of frequencies having different wave lengths $\lambda_1, \lambda_2, \lambda_3 \ldots \lambda_n$. Since the length of a side of the Ionocraft may be several hundred feet or greater, such construction is ideally suited for communication systems, whether operating with high or low frequencies.

With either of the configurations of FIGURE 11 or FIGURE 12, the view in elevation will be substantially as illustrated in FIGURE 10 where the particular antenna structure is indicated schematically and designated by reference numeral **92**. A ground station antenna which is indicated diagrammatically at **94** on FIGURE 10 may be provided for directing the signals downwardly to the ground station. Antenna **94** may be of any desired conventional type and connected on the Ionocraft to the main antenna structure **92** by a suitable transmission line such as coaxial cable, twin lead lines or hollow pipe waveguide, depending upon the particular frequencies utilized. Amplifiers or frequency converters may also be provided in the transmission line where signal strength is weak. The amplifiers and/or frequency converters may be powered by well known self-contained batteries or by the power supply unit for the Ionocraft (not shown).

Referring now to FIGURES 13 and 14 (Sheet 4), a further embodiment of the invention is illustrated which has a plurality of side sections, four of which are shown curved. The contour of the curves may be parabolic or of any other shape as is conventionally used for antennas in high frequency systems such as radar or the like. In this embodiment, an outside frame of lightweight rigid members **96**, **98**, **100** and **102** is provided to define the contour of the antenna shape. Lightweight wires or rods **104** extend between members **95** and **102** to serve as part of the antenna. Lightweight sheet metal of a material such as aluminum may be used in lieu of wires **104** for the reflector surface if desired.

A plurality of horns **106** are illustrated in the drawings to effect simultaneous radar scanning through 360°. By oscillating the illustrated Ionocraft about its vertical center line through an angle of only 45° on each side of a center position, complete 360° scanning may be effected. Alternatively, the Ionocraft may be rotated continuously about its vertical center line and 360° scanning effected by one or more antennas. Such scanning may be effected by warped corners, reactive or propeller blasts of auxiliary power plant, or by auxiliary grids which are mounted for movement relative to the main lifting grid as will be described below. Scanning may be effected by other means as will become apparent from the following description. In lieu of or supplemental to some of the microwave antennas **106**, antenna reflectors for infrared detectors may be carried on the Ionocraft. Such antennas serve to collect the infrared energy over a large area and focus such energy on a small infrared detector, and they may be of any conventional construction. The basic structure **10** between spaced antennas may contain such equipment to transmit via wireless signal channels to the ground station through ground station antenna **94**, signals corresponding to the electromagnetic and radio frequency signals received.

Horizontal movement of the craft may be effected by the principles set forth in Serial No. 760,390 of Glenn E. Hagen filed September 11, 1958, by tilting the craft downwardly in the forward direction whereby the ionic propulsion force provides a horizontal force component to cause the craft to move in a horizontal direction. Tilting of the craft may easily be effected through variation of the voltage between emitting electrodes **12** and collecting grid electrode **14**. For example, by electrically separating the craft into four sections of substantially equal size as illustrated in FIGURE 15 (Sheet 6), the voltage applied to two of the adjacent sections can be reduced by adding resistance in series with the current path and this will cause the lift produced by these two sections to decrease relative to the lift produced by the two other sections. Thus, horizontal movement of the craft may easily be controlled from the ground station.

For manual control of the posture and flight movement of the craft of the present invention, it has been found desirable to provide a control stick assembly which functions similar to that familiar to persons flying other types of aircraft. The control stick must function in both the longitudinal and lateral directions simultaneously and independently. Variable control elements such as potentiometers and variable transformers (powerstats for instance) may be used for control of the present invention. The posture of the craft may be controlled by dividing the collecting grid into three or more electrically separate regions as illustrated by the embodiment shown in FIGURES 6 and 7 and by individually varying the electrical potential to each of the separate regions. The potential may be increased to act as an elevator or may be decreased to act as a spoiler, and the voltage may be increased on one side while being simultaneously decreased on the other side to increase the effectiveness of the control.

Also, the emitting wires may be divided into three or more electrically separate regions and the electrical potential individually varied to each separate region. Again the potential may be increased or decreased, and may be simultaneously increased in one region and decreased in the opposite region.

To change the voltage to an individual region of the craft, a separate power supply for each region may be provided and the variable control element for changing the output voltage may be adjusted to produce the desired voltage level. Where a single power supply is provided, variable resistances may be placed in the electrical conductors leading to the appropriate terminals on the craft. If the craft is normally airborne with resistance present in the conductors, then increased voltage can be supplied to one region of the craft by decreasing the resistance in the conductor connected to that region. A decreased voltage can be supplied similarly by increasing the amount of resistance, and combination of increased and decreased voltages may be supplied to opposite sides of the craft to increase response of the craft to the controls.

One of the more simple ways to utilize the power supplied to the craft, I prefer not to have extra resistance in the power supply circuit of the emitting wires during normal flight and to control the posture of the craft by individually adding resistance into the circuit connected to each individual region of the collector grid. Such method of control has been found to provide adequate control of the Ionocraft and a control stick assembly will be described which utilizes variable resistance elements which are conventionally known as potentiometers or rheostats.

In FIGURE 16 (Sheet 5) the collecting grid construction as shown in the preceding embodiments (see for example FIGURES 6 and 7 on Sheet 3) is illustrated with each of the four grid sections W, X, Y, and Z connected through a separate correspondingly designated potentiometer to one terminal of the power supply. The emitting wires shown diagrammatically as waving lines are connected through a throttle control potentiometer, which is used to control the maximum voltage applied between the emitting wires and all of the collecting grid sections. When this voltage exceeds a certain level but yet remains less than that which causes arcing, the craft will rise. The effect of potentiometers A, B, C and D is to controllably reduce the voltage between the emitting wires and any one or two specific grid sections to thereby reduce or subtract from the effectiveness of that portion of the craft in producing its lifting force. This then causes the craft to tilt downwardly in the direction of whichever of the grid sections has the reduced voltage.

Referring now to FIGURES 17 and 18 (Sheet 5) front and side elevations of the control stick are shown with the respective shafts of the four potentiometers labeled A, B, C and D. On each of these shafts spur gears (not shown) are provided to be driven by gear segments secured to the stick.

The control stick is mounted for pivotal movement about pin P having axis X and about pin Q having axis Y beneath, but in the same vertical plane as axis X. Pin Q is mounted with its ends in opposite side walls W of the control stick housing.

The entire stick assembly shown in FIGURES 17 and 18 is mounted for unitary movement in a plane perpendicular to the longitudinal axis Y of pin Q. This assembly comprises bracket F which has secured to one side face spur gear G which need have only a segment thereof with teeth to mate with the pinion gears on the shafts of potentiometers B and D. The housings for potentiometers B and D are mounted on housing walls W, and the center of the gear segment on gear G coincides with axis Y of pin Q.

The ends of pin P are mounted in opposite sides of bracket B to enable the control stick to rock in a plane perpendicular to the longitudinal axis X of pin P. The lower end of the control stick is bifurcated as shown in FIGURE 18 and adapted to pivot about pin P. Gear segment H, having its center at axis X of pin P, is secured to the control stick for driving pinions on the shafts of potentiometers A and C which are mounted on bracket F.

The foregoing construction permits the control stick to function both in a longitudinal direction and in the lateral direction simultaneously to function as an electrostatic spoiler in the sense that when the craft is airborne, the addition of resistance in the lead-in wire to a particular grid section spoils the lift of that section to thereby control the posture of the craft in flight.

In the described embodiment, stick movement was limited to about 40° by mechanical stops not shown. The pitch diameter of each gear segment G and H was about 6 inches and the pitch diameter of the pinion gears on the potentiometer shafts was about 1 inch. The potentiometer gear shafts were capable of rotating through 240°, and were spring biased to a zero resistance condition.

As is apparent from FIGURES 17 and 18, the position of the pinion gears for the four potentiometers A, B, C and D is at the exact ends of the corresponding gear segments so that when the control stick is in its illustrated vertical position, each potentiometer is rendered ineffective to add any resistance to any of the collecting grid sections. As the control stick is tilted, one of the potentiometer shafts is rotated and there is absolutely no possibility that the potentiometer to the opposite grid section can be made effective at the same time because the partial gear segment and the spring loaded potentiometer shafts are used. The length of each gear segment must be at least as large as the maximum angle through which the stick can be moved, and the pinion gears are preferably at the precise ends of the gear segments.

It was found that if the potentiometer shafts were not spring loaded, the gears would upon occasion rotate slightly so the teeth did not always mesh when the stick was moved in a direction so that the gear segment should have engaged the potentiometer pinion. By the manual control stick just described, adequate tilt of the craft is readily achieved.

The position of the craft in air may be remotely controlled from a ground station through wireless control systems which may be of any suitable known type. The horizontal position of the craft may also be controlled automatically.

For example, the position of the craft of the present invention may be automatically controlled in space through means of suitable centering or tracking apparatus operating on well known principles, such for example as are disclosed in U.S. Patent Nos. 2,513,367 to Scott or 2,604,601 to Menzel. In such tracking apparatus, one form of which is diagrammatically illustrated in FIGURE 15 (Sheet 6), a beam of electromagnetic energy, such as light or infrared, is centered on a suitable photocell **128** which generates control signals that are used to control variable impedances to reduce the voltage applied to various sections of the craft to thereby control the position of the craft in accordance with the position of the beam source at the ground station.

FIGURE 15 illustrates in detail suitable horizontal positioning control arrangement. The common grid electrode **14** is connected to the negative terminal of the power supply and the emitting wires **12** are electrically separated into four sections, viz. left front LF, left rear LR, right front RF and right rear RR. Each of these sections is connected through variable impedances **130**, **132**, **134** and **136** respectively of the elevator control unit and the variable impedances **138** and **140** of the aileron control unit to the positive terminal of the power supply. The elevator motor **142** drives the movable contacts on variable impedances **130**, **132**, **134** and **136** and the aileron motor **144** controls in a similar manner values of the impedances **138** and **140**. Each motor **142** and **144** may be driven by separate amplifiers **146** and **148** and pre-amp **150** in a manner as conventionally used in servo systems to position photocell unit **128** directly in alignment with a source of electromagnetic energy positioned on the ground.

Referring now to FIGURE 19 (Sheet 2), a craft having a central cabin **160** and equipped with dihedral is illustrated. The collecting grid **14** and emitting wire **12** construction may be similar to that described in connection with FIGURE 4 (Sheet 2) and be positioned on alternate sides of cabin **160**. Beneath cabin **160**, a suitable wheeled, skid or pontoon landing gear **162** may be provided.

Depending beneath frame members **164** and on opposite sides of cabin **160** are a pair of auxiliary grid assemblies **166** and **167** that are mounted to be operable in a generally vertical plane. Each auxiliary grid assembly **166** and **167** is provided with laterally spaced emitting wires **168** and a collecting grid within outer frame members **170** so that upon receipt of a suitable D.C. potential, a horizontal thrust is provided in the manner hereinbefore set forth.

Each auxiliary grid assembly **166** and **167** is mounted on frame members **164** for independent rotational movement about substantially horizontal axes **172** and **173**. With the emitting wires **168** of both auxiliary grid assemblies facing in the same direction, the craft will proceed in the direction toward the emitting wires. With the emitting wires **168** of auxiliary grid assembly **167** facing in a rearward direction and emitting wires of grid assembly **166** facing in a forward direction as illustrated in FIGURE 19, the craft will revolve about an axis mid-way between the effective centers of the two grid assemblies. If the craft is simultaneously tilted in a cyclical manner, an effective radar antenna searching motion is provided which may include a large vertical angle as well as a 360° horizontal scanning operation.

Except where rotation of the craft for searching or scanning operations is a principal purpose for the craft, the emitting wires **168** of each auxiliary grid assembly **166** and **167** are mounted to face in the same direction. When landing or taking off, which is always accomplished in a vertical direction, auxiliary grid assemblies **166** and **167** are preferably pivoted into a horizontal plane. This not only retracts them to prevent interference with landing operations, but also provides a multiple deck structure to give additional lift and control of stability. Horizontal speed may be controlled by varying the angle of auxiliary grid assemblies **166** and **167** with the vertical.

As shown in FIGURE 20 (Sheet 6), the Ionocraft may comprise several decks **180**, **182** and **184** each of which is of similar construction to the single-decked craft shown in FIGURES 10–14 (Sheet 4). Each of the basic structures **180**, **182** and **184** may comprise different antenna types if desired. Several separate ground station antennas **186**, **188** and **190** may be provided particularly where independent signals are transmitted and received by the several antennas of the Ionocraft.

In FIGURE 21 (Sheet 2), a multiple decked craft is illustrated which comprises a central cabin **200** from which two lifting grid assemblies **202** and **203** extend laterally on opposite sides which are equipped with dihedral. Above grid assemblies **202** and **203**, one or more pairs of similar grid assemblies **204** and **205** are supported by a suitable superstructure **208**. The turning axes **212** and **213** for auxiliary grid assemblies **210** and **211** in this embodiment are substantially vertical and extend through support members **214** and **215** to the upper grid assemblies **204** and **205** to provide added rigidity to the craft structure. Retractable antennas **220** and **221** may be provided beneath cabin **200** for establishing communication channels to the ground station (not shown).

In general, it makes little difference whether the emitting wires **12** are connected to the negative or to the positive terminal of the power supply. By tests, it has been determined that with emitting wires **12** connected to the negative terminal, there is an improvement of about 5% over that obtained when the emitting wires **12** are connected to a positive terminal.

In the multiple deck constructions, it is preferable to connect emitting wires **12** and collector grid wires **14** of the adjacent decks to opposite terminals of the high voltage generator as illustrated in FIGURE 20 (Sheet 6), thus making discharge or emitting wires **12** in alternate decks positive and the collector grids negative which is the reverse of the polarity shown in FIGURE 1. In that case, tilting is effected by varying either the negative or positive potential of the corresponding emitting electrode wires and grid sections to provide a rolling movement longitudinally and laterally.

All the above mechanisms and procedures provided for manual control can be utilized for automatic control actuated by an automatic pilot director through suitable servo-mechanisms.

The tilting of the craft in the case of embodiments like those diagrammatically indicated in FIGURE 15 (Sheet 6) and 16 (Sheet 5) provides forward gliding movements much in the manner that a helicopter is propelled in a horizontal direction. Where other means are used for horizontal propulsion, such for example the auxiliary grids shown in FIGURES 19 and 21 or in conjunction with propellers or jet stream, then the tilting will be used to maintain a desirable posture in space. All these movements may be controlled automatically by conventional stabilizing and steering mechanisms borne by the craft or such movement may be accomplished from remote transmitting points either on the ground or from another airborne craft.

The maximum size of crafts of the type here involved is theoretically unlimited, except for structural considerations, since the amount of lift provided increases continuously with area. It is thus contemplated that a particularly useful function of the craft of the present invention may be to serve as means for destruction through collision oncoming vehicles and missiles through air and space. Intercontinental as well as space missiles enter the atmosphere over a target area in predictable trajectories, the terminal end of which is a substantially vertical path. Thus, the large horizontal area of the craft of the present invention is particularly suitable for the purpose of protecting sensitive target areas such as large cities, naval task forces, troop concentrations and the like by its mere physical presence during hovering operations. By maneuvering the craft laterally it is possible to protect an area much larger than the area of the craft since present detection systems give identifying information of the target area about 15 minutes prior to arrival of the missile and the lateral movement of the craft may be effected at speeds of the order of 60 miles per hour, or more depending upon the horizontal propulsion system used. If the target area is vast, several Ionocraft could be maintained aloft to assure collision with oncoming missiles.

While the craft may be powered through conductors extending from ground or ship towers or via microwave power transmissions, it is contemplated that lightweight power plants such as gas turbines or the like, be used to drive suitable high voltage generators which are aboard the craft. As shown in FIGURE 22 (Sheet 6), turbine **230** may be so mounted that its exhaust is directed vertically downwardly to provide additional lifting force while providing shaft rotation for producing the electrical power for the Ionocraft. Turbine **230** is here shown to be mounted for pivotal movement about the axis of shaft **232** which is driven by a tilt motor **234** to change the direction of the exhaust gases from vertical toward a horizontal direction. The entire tilt motor **234**, shaft **232** and turbine **230** assembly may be mounted to be rotated in azimuth by azimuth motor **236** driving annular ring gear **238**. Thus, in emergency operations where maximum horizontal speeds are desired, motors **234** and **236** may be controlled to advance the craft at higher velocities.

Other types of convention airborne power plants, such as turbine propeller combinations, may also be utilized for providing additional lift and aiding in maneuvering in the atmosphere. The turbine of FIGURE 15 may be provided with a reverse thrust device or such propellers may have a reversible pitch, and steering may be accomplished by rudders or vanes located in the jet stream of the turbine. Also, high voltage generation by radio-active isotopes is another method of obtaining the necessary high voltage energy or a primary source of ionization for the propulsion and sustenance of the Ionocraft.

It is also contemplated that this craft may be supplied with electrical power transmitted to the Ionocraft while in flight by microwaves. It has been demonstrated 80% of the energy emitted from a ground station microwave antenna array can be collected in the form of heat by airborne vehicles. In this case, such heat may be readily converted into high voltage by conventional means such as turbines operating high voltage generators, suitable thermocouples and vibrator-transformer convertors or the like. The use of high power microwave amplifiers, such as Amplitrons (Raytheon Co.), for power transmission via microwaves can provide the requisite power for a craft of this type. Therefore, it may be not essential that a self contained power unit be carried by the craft for special uses.

In the preferred form of the craft adapted for military purposes, directional detecting apparatus such as radar or infrared equipment will be carried by the craft to enable an antenna on the craft to lock-on any target object in air and space for the purpose of guiding the craft into the path of such oncoming target object. An Ionocraft of sufficient lift capacity may carry its own computers to process the electromagnetic information to provide the necessary impulses to the controls of the propulsive means to place the craft in the path of collision. Such craft may also be guided from the surface of the earth or from an airborne vehicle in flight, by remote control means to accomplish the collision with an oncoming object.

Explosives may be carried by the Ionocraft for destroying such oncoming objects if the mass of the Ionocraft is inadequate for destructive purposes. Such explosives may be of any known type and adapted to be detonated either upon impact or by proximity fuses where desired. Other types of countermeasures or defensive devices for causing premature explosions of the warhead of a missile may be carried by the Ionocraft as occasions arise.

The invention may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. The present embodiments are therefore to be considered in all respects as illustrative and not restrictive, the scope of the invention being indicated by the appended claims rather than by the foregoing description, and all changes which come within the meaning and range of equivalency of the claims are therefore intended to be embraced therein.

What is claimed and desired to be secured by United States Letters Patent is:

1. In combination with flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grids to provide a propulsion force for said flying apparatus, and antenna means for use with radio frequency energy signals, said antenna comprising a plurality of elements which serve also as part of said structure for the flying apparatus by being connected electrically to one terminal of said high D.C. potential to assist in providing propulsion force for said apparatus.

2. In combination with flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus, an antenna for use with radio frequency energy signals, said antenna comprising a plurality of elements which serve also as part of said structure for the flying apparatus by being connected electrically to one terminal of said high D.C. potential to assist in providing propulsion force for said apparatus, and the flying apparatus structure having a configuration such that at least one side has a length greater than one-half the wave length of the radio frequency energy transmitted by the antenna.

3. The combination as defined in claim 2 wherein said antenna comprises a plurality of conductive elements having differing lengths whereby said antenna is tuned to different frequencies of radio frequency energy.

4. The combination as defined in claim 2 wherein said antenna comprises elements which serve as part of the mechanical structure of the neutralizing grid.

5. In combination with flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus, said flying apparatus having on a plurality of different sides thereof antenna means for directional transmission of radio frequency signal energy, the length of a side being greater than one-half the wave length of the signal energy being transmitted, and means for effecting a scanning movement of said antenna means by rotating said flying apparatus about a vertical axis.

6. In combination: flying apparatus comprising a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus; said apparatus being divided electrically into different sections with separate circuits individual to each of said sections for connecting said D.C. potential to the electrodes of the respective section; means including highly directional radiant energy sensitive means on said flying apparatus for receiving energy from an electromagnetic energy source at a control station, mounted on said apparatus for generating control voltages; and circuit means for connecting said control voltages to impedance varying means to reduce the voltage to various ones of the sections of said apparatus to cause said apparatus to assume a position determined by the energy source at said control station.

7. A system and apparatus for effecting destruction of flying vehicles including a flying apparatus composed of a large area structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means which neutralize the charge on electrically charged molecules whose charge was caused by said discharge electrode

and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus; tracking means carried by said flying apparatus for generating control signals, means responsive to said control signals for guiding said flying apparatus into the path of said flying vehicles and to effect destruction thereof by impact.

8. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, structural supporting means for said neutralizing grid separating said grid into two substantially equal sized grid areas, and means securing said grid areas in an angularly related position to equip said apparatus with dihedral for stabilization.

9. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, structural supporting means for said neutralizing grid separating said grid into two pairs of grid areas, the grid areas of each pair being of substantially equal size and on opposite sides of the apparatus, and means securing the grid areas of each pair in an angularly related position to equip said apparatus with dihedral in both longitudinal and lateral directions.

10. The apparatus as defined in claim 9 wherein each grid area is planar and the center of the craft is higher than the outer peripheral edges to thereby provide a negative dihedral.

11. The apparatus as defined in claim 9 wherein each grid area is planar and the center of the craft is lower than the outer peripheral edges to thereby provide a positive dihedral.

12. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, the improvement wherein the collecting grid comprises a plurality of lightweight thin walled tubes having an outer surface of conductive material, said tubes being inflated and spaced to provide neutralization of the charged particles and permit air flow between adjacent tubes.

13. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, the improvement wherein the discharge electrodes comprise wires of conductive material mounted above the neutralizing grid, and a plurality of short wires mounted on the discharge electrodes with free ends thereof suspended beneath the discharge electrodes at substantially equal distances from said neutralizing grid to thereby provide point sources for causing ionization.

14. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, an auxiliary discharge electrode and neutralizing grid structure supported by said flying apparatus for movement relative to said flying apparatus about a pivot axis for controlling the posture and direction of movement of said apparatus.

15. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, a pair of auxiliary discharge electrode and neutralizing grid structures supported at spaced positions on said flying apparatus, each of said grid structures being mounted for movement about pivot axes for controlling the posture and direction of movement of said apparatus.

16. Apparatus as defined in claim 15 wherein said pivot axes are in a horizontal plane.

17. Apparatus as defined in claim 15 wherein said pivot axes are vertical.

18. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, a rigid frame for said neutralizing grid including intersecting support members lying in a vertical plane, and air foil means secured to said intersecting support members to provide added stabilization to said apparatus.

19. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus, a polygonal rigid inner and outer frame for said neutralizing grid, a center portion of said grid surrounded by said inner frame being without the electrical conducting means forming the grid, and diagonally disposed frame assemblies extending between corners of said outer frame and said inner frame.

20. Apparatus as defined in claim 19 wherein the apparatus is provided with negative dihedral and the center portion is covered with an air foil to provide a pressure wave beneath the craft for added lift.

21. In combination a base member; bracket means supported on said base member for movement about a first pivot axis; a first gear segment on said bracket; a first pair of electrical circuit elements having parameters which are variable in magnitude by rotation of a shaft individual to each circuit element; a gear on each of said shafts; said gears being positioned at opposite ends of the gear segment on said bracket so that only one shaft is rotated from a reference position at any moment; a control stick mounted for pivotal movement on said bracket about a

second pivot axis perpendicular to said first pivot axis; a second gear segment on said control stick; a second pair of electrical circuit elements similar to said first pair of electrical circuit elements mounted on said bracket means; and separate gears for controlling said second pair of electrical circuit elements, said gears being mounted at opposite ends of said second gear segment so that only one gear is rotated from a reference position at any moment.

22. The combination as defined in claim 21 wherein each electrical circuit element contains a shaft spring loaded to a reference position.

23. The combination as defined in claim 22 wherein the electrical circuit elements are variable resistances.

24. The combination as defined in claim 23 together with flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode, said grid comprising four electrically isolated sections of substantially the same size, and means for connecting one terminal of a high D.C. potential source to said electrodes and a second terminal to each of the four sections of said grid through different ones of said variable resistances.

25. In apparatus for thrust generation in atmosphere, composed of spaced emitting and collecting electrodes energized with a voltage sufficiently high to be capable of causing ionization for effecting an ionic discharge from an emitting electrode to produce thrust on at least one of the electrodes of said apparatus arising from elastic molecular and particle collisions occurring in the space between said electrodes during molecule and particle movement in the direction from the emitting electrode to the collecting electrode, said collecting electrode being composed of crossed grid wires of conductive material forming an open surface that is generally normal to the direction of molecule and particle movement, the improvement wherein said crossed grid wires have a diameter of at least 8 mils.

26. The apparatus as defined in claim 25 wherein the collecting electrode ends are covered by a layer of conductive material.

27. In flying apparatus composed of a structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means for neutralizing the charge on electrically charged molecules whose charge was caused by said discharge electrode; and means for applying a high D.C. potential between said electrodes and said grid to cause air to move from said electrodes toward said grid to provide a propulsion force for said flying apparatus; the improvement wherein said neutralizing grid comprises outer peripheral frame members and a centrally positioned inner frame between which the conducting means comprising the neutralizing grid are mounted, and which are positioned in different horizontal planes to thereby provide the craft with dihedral; and said discharge electrodes comprise a plurality of substantially parallel wires, each mounted parallel to the outer peripheral frame members and in different horizontal planes so that all wires are substantially aquidistant from said neutralizing grid.

28. A system and apparatus for effecting destruction of flying vehicles including a flying apparatus composed of a large area structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means which neutralize the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus; auxiliary discharge electrode and neutralizing grid means mounted for pivotal movement for controlling the forward direction of movement; tracking means carried by said flying apparatus for generating control signals, means responsive to said control signals for guiding said flying apparatus into the path of said flying vehicles and to effect destruction thereof by impact.

29. A system and apparatus for effecting destruction of flying vehicles including a flying apparatus composed of a large area structure supporting discharge electrodes for causing adjacent air molecules to become electrically charged spaced from a grid of electrical conducting means which neutralize the charge on electrically charged molecules whose charge was caused by said discharge electrode and means for applying a high D.C. potential between said electrodes and said grid to provide a propulsion force for said flying apparatus; a gas turbine mounted on said apparatus with its exhaust gases directed downwardly during hovering operation and means for deflecting said exhaust gases in a direction providing a horizontal propulsion force to increase to the forward velocity of said apparatus; tracking means carried by said flying apparatus for generating control signals, means responsive to said control signals for guiding said flying apparatus into the path of said flying vehicles and to effect destruction thereof by impact.

IONOSPHERIC BATTERY

Leslie G. Smith, Waltham, Mass., assignor, by mesne assignments, to the United States of America as represented by the Administrator of the National Aeronautics and Space Administration

Filed Mar. 9, 1962, Ser. No. 178,721
11 Claims. (Cl. 310—5)

This invention relates to a method and apparatus for tapping the enormous reservoir of energy existing in the ionosphere and more particularly for furnishing electrical power to space vehicles.

Within recent years various space probes and space vehicles such as satellites have been launched by man in an effort to learn more about the earth and the solar system within which he lives. Each of these various space craft has employed numerous electrical circuits which are utilized to detect and transmit back to earth certain information ascertained by the craft as it moves through space. In view of the presence of such electrical circuits, some source of electrical power must be made available whereby these circuits can be energized. In the past there have been three main sources of electrical power carried by space vehicles for energizing these circuits, namely, (1) conventional storage batteries, (2) solar batteries and (3) a combination of the conventional storage and solar batteries. Although these various electrical power sources have functioned with some degree of success each has certain serious limitations which cannot be readily overcome.

In the first instance, the conventional storage battery may be of either the wet or dry type but, due to its superior storage capacity, the wet cell type is used nearly exclusively in space vehicles. This additional storage capacity of the wet cell battery is of great importance since the useful life of the vehicle is usually dependent upon the proper operation of its electrical circuits which are, in turn, directly dependent upon the capacity and life of the available power source. Use in space vehicles of a storage battery that utilizes a liquid electrolyte presents several problems that have not been completely solved, however, nor is there any apparent solution to some of these problems. For example, to increase the output capacity of the battery and thereby extend the useful life of the satellite a greater amount of electrolyte must be carried by the battery. But to increase the quantity of electrolyte carried by the battery results in both an increase in size and weight of the power source and space vehicle which cannot, in most instances, be tolerated. Furthermore, the electrolyte may not function correctly if it is subjected to the extreme conditions of space such as, for example, the changes in temperature that are normally encountered. Thus, to insure the proper operation of the wet cell battery involved in powering a space vehicle and to prevent any leakage that might occur should the battery be damaged, some shielding or insulating of the battery is usually involved which, needless to say, adds materially to the cost and weight of the vehicle.

To overcome the space, weight and leakage problems encountered when storage batteries of the conventional wet cell type are used, space engineers have turned to the recently developed solar cell or battery which converts the light rays received from the sun directly into electrical energy. While these solar batteries do not require any type of electroylte and are, therefore, relatively light in comparison to the wet cell storage battery, they are expensive and their inherent principle of operation presents one problem which cannot be overcome, namely, the inability of the solar cell to produce power while the space vehicle is shaded from the sun such as occurs when a satellite is in the shadow cast by the earth.

In an effort to overcome this loss of power which occurs each time a satellite passes into the shadow cast by the earth or some other heavenly body, a storage battery of the wet cell type was added to the vehicle. While the satellite is in the sunlight the solar battery powers the various electrical circuits and charges the storage battery so that, once the sunlight is no longer available, the storage battery can be switched on to furnish the necessary electrical power to the vehicle. While this combined system functions satisfactorily, there is added to the already existing problems of weight, size and electrolyte leakage the problem of incorporating a battery charging and switch-over system between the solar and storage batteries. The addition of this type of system to the power source is undesirable since it adds unduly to the complexity, sensitivity and cost of the space vehicle.

According to the present invention, it has been found that some of the foregoing disadvantages of space vehicle power sources can be overcome by employing an ionospheric type battery which utilizes the ionosphere or other ionized medium existing in outer space as a supplemental source of energy. Since power is a scarce commodity essential for the operation of the space vehicle and for the proper functioning of its experiments, any means for supplying additional power while adding only slightly to the weight of the vehicle, increases the efficiency and life of the space vehicle. Although it has been known for some time that the ionosphere contains an enormous reservoir of energy in the form of excited and ionized atoms and molecules, no practical method has heretofore been found whereby this energy could be utilized as a source of power for earth satellites even though much thought has been given to this problem. The operation of the present invention is based upon the discovery that the ionosphere can be utilized as a part of supplemental power source for the load circuit in a space vehicle when said vehicle is equipped with electrodes having different work functions which, in turn, are electrically connected through the load circuit.

Accordingly, a primary object of this invention is to provide a method of producing electrical power from ionized media existing in nature.

Another object of this invention is to provide a simple, highly reliable supplemental power source for space vehicles.

Yet another object of this invention is to provide an ionospheric battery for use by satellites.

Still another object of this invention is to provide an ionospheric battery which utilizes the ionosphere as an electrolyte.

A further object of this invention is to provide a supplemental power source for space vehicles that will operate when shielded from the sun.

Yet a further object of this invention is to provide a power source for a satellite that is light and inexpensive to produce.

Another object of this invention is to provide a satellite with various shaped electrodes constructed of metals having different contact potentials.

These and further objects and advantages of this invention will become more apparent upon reference to the following description, claims and the appended drawings wherein:

FIGURE 1 is a cross sectional view of an orbiting satellite equipped with a power source constructed in accordance with one embodiment of the present invention; and

FIGURE 2 is a view in partial section of an orbiting satellite equipped with a power source constructed in accordance with a second embodiment of the present invention.

With continuing reference to the accompanying drawings wherein like reference numerals designate similar parts throughout the various views, and with initial attention directed to the embodiment of FIGURE 1, reference numeral **10** is used to generally designate a space satellite which is orbiting or otherwise passing through an ionized layer or medium such as, for example, the ionosphere which surrounds the earth. As is well known, the ionosphere contains an enormous number of excited and ionized atoms and molecules which are generated or produced when the gasses surrounding the earth are subjected to bombardment by high energy particles and rays such as, for example, ultra-violet or cosmic rays that originate throughout the solar system. Although these various ionized particles created by this bombardment are invisible to the eye they are represented pictorially by the various dots **12** for purposes of clarity.

The satellite **10** consists of an envelope or outer skin surface **14** which may be constructed of metal, ceramic or any other like material which is suitable for space vehicles of this type. As seen in FIGURE 1, a plurality of electrically conductive electrodes **16–18**, which are shown in the form of rods and are constructed of materials having different contact potentials (work functions), are mounted in a spaced relationship in the medium **12** through apertures **20** in the envelope **14** of the satellite. In order to prevent a leak from occurring between the normally pressurized interior **22** of the satellite and the ionosphere, which is a near vacuum, and to insulate the electrodes in case a metal is used for the envelope **14**, vacuum tight insulator feed-through elements **24** are fitted around the electrodes **16–18** and are securely mounted within the aperture **20**. These feed-through elements may be of any suitable type so long as they are constructed to withstand the changes in environmental conditions encountered in space without losing their insulative and sealing qualities.

Carried within the cavity or interior **22** of the satellite **10** is a load circuit **26** which may be, for example, a transmitter or any other electrical device that requires a source of electrical power for its proper operation. The load circuit **26** is mounted to the interior wall of the satellite by suitable means (not shown) and has its positive and negative power input terminals **28–30** connected to the various electrodes **16–18** respectively, by suitable electrical conductors **32–34**.

The overall principle and operation of the ionospheric battery in relationship to the satellite **10** can be explained substantially in the following manner. While the satellite remains on earth prior to its being hurled into or through an ionized medium, the electrodes **16–18** are at substantially the same potential since very few ionized particles are present. Thus, no current will flow through the load circuit **26**. However, once the satelllite is launched and it enters an ionized medium a potential difference will be established between the electrodes **16–18** and an electrical current will begin to flow through the load circuit **26**. This difference in electrical potential that exists between the electrodes **16–18** while the satellite is in an ionized medium is attributed to the fact that the electrodes **16** are constructed of a material having a different contact potential or work function from that of the electrodes **18**. This difference in contact potential between the electrodes **16–18** will result in the free electrons of the ionized medium being collected on one group of electrodes, for example the electrodes **16**, while the positive ions produced when the gas is ionized will be collected on the other electrodes **18**. With the electrodes **16** charged to a negative potential in relationship to electrodes **18**, a predetermined amount of current will flow through the load circuit **26** and can thus be utilized to power an electrical circuit such as the transmitter mentioned above.

The exact material from which the two types of electrodes **16** and **18** are constructed will depend upon several factors such as, for example, the amount of output power desired, the material readily available for constructing the electrodes, the susceptibility of the material to damage or destruction when exposed to the environmental conditions existing in space, and various other considerations that will be readily apparent to a worker in the battery field.

While the electrodes **16–18** used in the ionospheric battery of FIGURE 1 have been described as rods or whip-like elements it is to be realized that the electrodes may take other shapes. By way of example, a plurality of flat, plate-like electrodes **36–38** are shown mounted on a satellite in FIGURE 2. These electrodes are constructed of materials having different contact potentials and are insulated from the outer surface **14** of the satellite when this is necessary by an insulative layer **40** of any suitable material having the desired insulative properties under the severe conditions existing in space. The use of these plate electrodes **36–38** has the advantage of increasing the surface area exposed to the ionized medium thus permitting a larger output current to be produced without the necessity of using excessively long electrodes as might be the case if the rod electrodes of FIGURE 1 were used.

The output current of the battery is dependent upon the degree to which the medium is ionized and to the extent that the electrode surface area is exposed to the medium. An increase in either results in an increase in the efficiency of the battery. From an analysis of various experiments it is expected that a current of about two microamps per cm.^2 of electrode surface at a potential of one volt would be produced if the satellite is orbiting in the ionosphere at an altitude of approximately 350 km. and electrodes of gold and platinum are used.

It will also be readily apparent that the envelope of the satellite itself could be constructed in sectional form and of materials having different contact potential thus eliminating the necessity of attaching different electrodes to the satellite or the slight increase in weight necessarily involved. Of course the various sections of material making up the envelope of the satellite would have to be insulated from one another to prevent electrical shorting from occurring.

It will be apparent from the foregoing that the power source of this invention is extremely light, rugged and involves a minimum of cost to construct. By using the vast natural reservoir of energy existing in the form of ionized gases for producing the electrical power necessary to energize the various electrical circuits of a space vehicle a practically indefinite source of electrical power is made available to the vehicle. An ionospheric battery constructed in accordance with this invention is also much more reliable in operation than other heretofore known power sources since no liquid electrolyte is involved which can leak, deteriorate or otherwise become spent, nor is the operation of the battery dependent upon its position in relationship to a source of light.

The invention may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. The present embodiments are therefore to be considered in all respect as illustrative and not restrictive, the scope of the invention being indicated by the appended claims rather than by the foregoing description, and all changes which come within the meaning and range of equivalency of the claims are therefore intended to be embraced therein.

What is claimed and desired to be secured by United States Letters Patent is:

1. A space vehicle equipped with a generator of electrical energy operable in the ionosphere as a supplemental source of potential for a load thereof, said generator comprising at least two electrode means on said vehicle and positioned to contact said ionosphere when said vehicle is in said ionosphere, said two electrode means each having different contact potentials, one of said two electrode means being gold and the other being

platinum, and electrical connector means connecting said two electrode means to said load.

2. Apparatus for generating electrical energy from the ionosphere comprising, a pair of spaced electrode means having different contact potentials positioned to contact said ionosphere so that a direct-current electric potential is established between said electrode means, load circuit means, and means electrically connecting said load circuit means to said electrode means whereby said load circuit means is powered by the direct-current electrical potential existing between said electrodes.

3. Apparatus for generating electrical energy from the ionosphere comprising, carrier means, a first electrode having a first contact potential mounted on said carrier means, a second electrode having a second contact potential spaced from said first electrode and mounted on said carrier means, said first and second electrodes being positioned on said carrier means so that they will be in contact with said ionosphere when said apparatus is placed in the ionosphere so that a direct-current electric potential is established between said first and second electrodes, and an electrical load circuit connected between said first and second electrodes, said load circuit being powered by the direct-current potential produced by said first and second electrodes.

4. Apparatus according to claim 3 wherein said first and second electrodes extend away from said carrier means.

5. Apparatus according to claim 3 wherein said first and second electrodes form a portion of said carrier means.

6. In a space vehicle adapted to pass through ionized areas in space, a power source for said vehicle while it is passing through said ionized areas comprising, a plurality of electrode means located on the outer surface of said vehicle, said electrode means being constructed of materials having different contact potentials, and means connecting said electrode means together through a load circuit whereby said circuit receives a source of direct-current as said space vehicle passes through said ionized areas.

7. In a space vehicle according to claim 6 wherein said electrode means are rod shaped.

8. In a space vehicle according to claim 6 wherein said electrode means are plate shaped.

9. A satellite comprising an envelope, electrical load means carried in said envelope, apertures extending through said envelope at spaced points, electrode means

having different contact potentials, said electrode means passing through said apertures, means in said aperture for insulating said electrode means from said envelope, and electrical conductor means connected between said electrode means and said electrical load means whereby said electrical load means is energized by the direct-current electric potential established when said electrode means passes through an ionized medium.

10. A space satellite comprising an envelope, an electrical load circuit carried in said envelope, a power supply for said electrical load circuit comprising a first electrode having a first contact potential connected to said electrical load circuit and extending through said envelope and a second electrode having a second contact potential connected to said electrical load circuit and extending through said envelope, said first and second electrodes being insulated from one another so that said electrical load circuit is powered by the direct-current electric potential established by said first and second electrodes coming in contact with an ionized medium.

11. The method of powering electrical circuit means carried by a space vehicle comprising the steps of positioning first and second electrode means having different work functions on said vehicle, passing said vehicle through the ionosphere so that said first and second electrode means are in contact therewith and produce a direct-current potential between them, and connecting said first and second electrodes to said electrical circuit means by means of electrical connector means, whereby said direct-current potential is made available for operating said circuit.

ABSTRACT OF THE DISCLOSURE

A combined antenna and conversion mechanism for reception of beamed high frequency electromagnetic energy in space including a large array of unidirectional current semiconductor rectifier devices. A self-supporting space vehicle utilizing the rectified DC electrical energy for propulsion is disclosed in an illustrative embodiment.

The present invention relates in general to the transfer of energy by means of an electromagnetic wave beam and more particularly to interception and rectification of such energy into low frequency electrical DC energy with a high degree of efficiency.

Improved technology in the field of microwave energy generation at superpower levels has resulted in the realization of electrical energy transmission over considerable distances for remote energization of devices or vehicles without the aid of wires. The transmission of microwave electromagnetic energy into space has been commonly employed in the radar pulse echo systems for the detection and orientation of desired objects within a predetermined scanning range of a transmitting antenna. Beams of a similar nature may now be employed for other useful purposes and the advantages attendant the utilization of electromagnetic energy in the microwave region in contrast with other wavelengths may now be enumerated.

Microwaves have been generally defined as high frequency radio waves whose wavelength is less than 30 centimeters, with a lower wavelength limit on the order of 1 millimeter sometimes being applied to what is commonly referred to as the "microwave region." The superiority of high frequency microwaves is due in part to the fact that it is generally desirable to focus the transmitted energy so as to achieve a high power density at a remote point or area with respect to a given power source. In accordance with the laws of optics, the sharpness of the microwave beam produced by a transmitting antenna varies as the ratio of antenna dimensions to the wavelength of the transmitted energy. Therefore, for a given or desired power density or beam sharpness, a decrease in the wavelength of the transmitted energy permits a corresponding decrease in the dimensions of the antenna. From the standpoint of mechanical considerations, it is desirable to employ small antennas and other components, and it is therefore advantageous to employ high frequency energy of very short wavelength. In addition, the difficulties encountered in long wave transmission as a result of natural and man-made interference or noise do not occur with any appreciable significance at microwave frequencies. Further, in aerospace applications with considerable distances separating the transmitter at an earth or mother planet location and the employment of shorter wavelength beamed energy is preferred since longer wave signals will generallly be reflected at certain altitudes by reflecting layers in the atmosphere.

In view of certain losses due to absorption which may occur in the atmosphere, microwaves in the region having the approximate bounds of 2 and 30 centimeters are readily adaptable to the convenient radiation of power to remote points without the utilization of wires. The preferred wavelengths are of the order of 5 or 10 centimeters to provide efficient focusing with existing transmitting antenna systems which may be maintained at a reasonable size. An illustrative device of the superpower high frequency microwave generators operative in the desired band is the so-called Amplitron which is an amplifier having a broad bandwidth and excellent performance characteristics for the focusing of the beam. Such devices are capable of producing 15 or 20 kilowatts of average continuous wave power in the neighborhood of 10 centimeters in wavelength with capabilities expected in the region of 500 kilowatts or more average power with 50 megawatts peak power. A complete description of such devices may be had by referring to Patent No. 2,933,723 issued Apr. 19, 1960 to William C. Brown and assigned to the assignee of the present invention.

With microwave energy capable of being generated and directed over longer distances conversion of such high frequency electromagnetic energy is of paramount concern. One conversion mechanism in the prior art involves direct conversion of such energy into heat which may then be utilized directly or indirectly for propulsion or generation of flight-producing forces. Examples of such devices for heat energy exchange as well as space vehicles utilizing such energy may be noted in Patent No. 3,174,705, issued Mar. 23, 1965, to D. Schiff et al., as well as U.S. Letters Patent No. 3,083,528, issued Apr. 2, 1963 and No. 3,114,517, issued Dec. 17, 1963, to William C. Brown. The heat exchanger method of conversion of electromagnetic energy into useful power is limited by the overall efficiencies of approximately 25 percent in the conversion of heat into mechanical or electrical work. Desirable, therefore, would be the direct rectification of the high frequency electromagnetic energy into low frequency electrical energy for the operation of many useful aerospace devices as well as systems.

The present invention has for its primary object the conversion of high frequency electromagnetic energy in the microwave region directly into low frequency electrical energy.

A further object of the present invention is the provision of a combined nondirectional receiving antenna and microwave electromagnetic energy to low frequency electrical energy conversion means in a unitary structure.

A still further object of the present invention is a provision of a new and novel combined nondirectional receiving antenna and microwave to DC energy converter for aerospace applications.

Another object of the present invention is the provision of a new and novel nondirectional receiving antenna and microwave to DC energy converter having a high degree of efficiency.

Still another object of the present invention is the provision of a new and novel aerospace vehicle with nondirectional receiving antenna and microwave to DC energy converter means with said vehicle being capable of being supported by its own energy generation means at a distance spaced apart from the power generation means.

In accordance with the teachings of the present invention, the above and other objects are achieved by the employment of efficient unidirectional microwave power rectifiers and dipole antenna means. Such rectifying devices, while being individually limited in power-handling capabilities, normally in the order of fractions of watts, have been found to be highly efficient means for the rectification of microwave power when assembled in large numbers in various arrays. It is interesting to note that the observed collective efficiency was on the order of 40 to 70 percent. In an illustrative embodiment, point-

contact semiconductor diodes were arranged in four arm bridge connected networks with the networks interconnected in various configurations such as series, parallel and series-parallel.

In discussing aerospace applications, an additional problem is encountered in the beaming of microwave energy to a remote point and the interception and utilization of such electrical energy. In such applications the advantages of a vehicle which may be maintained in space for indeterminate periods of time without employing a local fuel source are readily apparent. Such devices could readily provide communication networks, surveillance functions using radar techniques along with numerous other functions. The acapture of the beamed high frequency electromagnetic energy raises the need for an efficient antenna means capable of intersecting the beam at high altitudes. Conventional techniques employed in microwave radar usage such as receiving antenna horns are capable of intersecting only a small portion of the beam energy and add considerable weight in applications involving heavier-than-air vehicles. In an exemplary embodiment of the invention a space vehicle, namely a helicopter, is disclosed for either moving flight or a stationary location with self-supporting electrically operative propulsion means. The semi-conductor diode rectifier arrays have been demonstrated to fulfill the receiving antenna functions as well as the electrical energy rectification means in a highly efficient manner. Such combined antenna and rectifier means has also assisted in reduction of the weight problem in airborne devices. Further, it has provided a nondirectional means for the interception of the microwave energy to thereby reduce the problems of focusing inherent in prior art directional horn type receiving antennas.

With the above features, advantages and objects in mind the invention will now be described by reference to the following detailed description together with the accompanying drawings in which:

FIG. 1 is a perspective view of an illustrative diode rectifier;

FIG. 2 is a schematic circuit diagram of a bridge connected diode network with dipole antenna means;

FIG. 3 is a schematic circuit diagram of a plurality of bridge connected networks arranged in series;

FIG. 4 is a schematic circuit diagram of a parallel bridge connected network array;

FIG. 5 is a perspective view of an illustrative embodiment of a combined antenna and rectifier array in a folded or rolled up configuration;

FIG. 6 is a schematic circuit diagram illustrating the bridge connected diode array incorporated in the aerospace vehicle shown in FIG. 7;

FIG. 7 is a schematic representation in elevation illustrative of a heavier-than-air aerospace vehicle incorparating the structure of the present invention;

FIG. 8 is a perspective view of the aerospace vehicle embodiment as viewed from the under portion thereof; and

FIG. 9 is an enlarged partial view in elevation of a portion of the illustrative embodiment shown in FIG. 8.

FIG. 1 illustrates a point-contact semiconductor diode rectifier of the type employed in radar microwave receiver apparatus to rectify returned radar pulses. Any of the high burnout semiconductor diodes having high rectification characteristics are preferred and are commercially available, such as the 1N82 or 1N830. The rectifying junction is formed by whisker element **2** contacting the semiconductor element **4** respectively connected to leads **6** and **8**. Silicon is preferred over germanium for element **4** because of its ability to operate at higher temperatures and thereby handle higher powers. Envelope **10** houses the rectifying elements and may be of a hermetically sealed dielectric material or combination metal and ceramic composition. The inherent characteristic of such diode rectifiers is that the microwave energy is intercepted and rectified in a unidirectional manner and the line **11** indicate pictorially the rays of the beamed electromagnetic microwave energy in a plane normal to the envelope. In FIG. 2 a full-wave bridge connected diode network is illustrated with the forward direction of the rectified DC electric current indicated by the direction of the arrow symbols. The network shown consists of half-wave dipoles **20** and **22** each terminated with a diode rectifier element **24** to **27** in an arm of the bridge connected network. The dipole elements **20** and **22** are of the half-wave configuration and may be spaced apart from each other a one-half wavelength at the frequency of the beamed electromagnetic energy.

Referring now to FIG. 3, an array of bridge connected diode networks each with the half-wave dipoles are shown connected in series. Each network is referred to by the numeral **30** and is similar in the bridge connections to the single element network shown in FIG. 2. The DC output of the collective rectified energy is coupled by means of terminals **32** and **33**. In FIG. 4, a similar number of individual bridge connected diode-dipole networks are shown connected in a parallel array. Each network is indicated by the numeral **40**, and the output terminals are indicated as **41** and **42**.

Any number of diode-dipole networks may be provided and in FIG. 5 such a multi-element array is illustrated by mounting on a flexible material **50** which may be rolled or folded into any desired package or enclosed within a capsule to be launched and released at a predetermined point in space. Any flexible material which is pervious to electromagnetic energy is preferred. The total power desired would be the determining factor in a number of individual diode-dipole elements required. In this embodiment, the bridge connected networks **51** are connected in parallel to the output load indicated by terminals **52** and **53**, and representative measurements of electrical characteristics have shown that approximately five watts of DC electrical energy is realizable for each square foot of area of the combined antenna-rectifier. While the dipole elements **54** have been indicated in a particular array, it is within the scope of the invention to stagger the placement of such dipoles to increase the over-all efficiency of the antenna-rectifier.

To further increase the DC powder output, the full-wave bridge connected networks are preferably arranged with a plurality of diodes in series in each arm of the bridge. An illustrative schematic circuit diagram of such a configuration is shown in FIG. 6 wherein seven diodes **60** are shown in each arm of the bridge circuit and are connected in series for a total of twenty-eight diodes in each bridge network. The dipole members will then be the substantially U-shaped end portions **61** at the ends of each brace of seven diodes. In the illustration three such twenty-eight diode bridge networks are shown connected in parallel to terminals **62** and **63**. This closer spacing and compact arrangement has been shown to be a source of improved power output and is capable of a high degree of reliability through the redundant nature of the parallel series connections within each bridge network. If one of the diode rectifiers fails to function the over-all voltage drop across this element would be divided among the six remaining diode rectifiers. If any of the connecting wires between the diode elements should break, the adjacent arms of the other bridge assemblies would take the additional load due to the close proximity of the respective arms to each other. In addition, it is possible to have a number of open connections or inoperative diodes dispersed throughout the array without any serious impairment in performance.

In relation to the array concept to be hereinafter described it may be stated that within a six inch square area ten such individual bridge networks each containing twenty-eight diode rectifiers for a total of 280 diode rectifiers may be deployed in such a manner as to provide

maximum exposed area for each diode as well as the connecting leads. Such an arrangement will be hereinafter referred to as a "module" and a DC output in excess of fourteen watts has been measured for such a module. Any number of such modules could be connected provided for a desired power yield and this module concept readily lends itself to use in certain aerospace applications now to be described.

In FIG. 7 a propelled type of space vehicle **70** is shown wholly supported by means of the transfer and rectification of continuous wave electromagnetic energy via a microwave beam **72**. The source of the microwave energy which may be of the Amplitron type device as described in the aforementioned issued Patent No. 2,933,723 is indicated as **74**. This energy is fed by waveguide means **76** to a transmitting horn **78** to illuminate an ellipsoidal beam forming focusing antenna **80** for the transmission of the microwave beam **72**. It will be appreciated by those skilled in the art that the representations of the microwave generation and transmitting antenna means are pictorial representations to illustrate the usage of the invention in diagrammatic form and the present invention is not limited to any particular source of microwave energy or transmitting antenna assembly. It may be stated the reflector of the antenna assembly is considerably larger than most of the reflectors of the prior art in order to focus a large amount of the microwave power at high altitudes for use in the transfer of energy to space vehicles. Such antenna assemblies may be partially supported in a large hollowed area on the earth's surface or other convenient means of support.

The space vehicle or helicopter **70** can be described as a main body member supporting antenna-rectifier means **82** including a large number of the so-called modules connected together and rigidly supported in a planar parallel array. A motor **84** is supported by the combined body member and the receiving antenna-rectifier means and actuates the rotor **86** of conventional design employed in such self-propelled hovering vehicles. The disclosed vehicle provides for the illumination of the planar array of the semiconductor diode dipole elements by the microwave beam and the direct conversion of the microwave power transmitted by the beam into usable electrical energy for the self-propulsion of the device without any local fuel supply being required.

FIGS. 8 and 9 illustrate a space vehicle **82** comprising a plurality of the combined receiving antenna-rectifier module means for interception and rectification of the electromagnetic microwave energy beam emanating from an earth or mother planet source. A planar array of the antenna-rectifier modules is mechanically supported by means of structural members **90** of any lightweight wood or metal. Insulators **91** positioned coextensive with the members **90** support the diode rectifier array and avoid interference with the receiving and electrical performance characteristics by the structural support members. Carrying forward the module concept of 280 diode rectifiers to provide an approximate power output of 14 watts, it was noted that any number of such modules may be coupled together since the individual module outputs are relatively insensitive to a wide range of load resistances connected to the common output terminals. To achieve the desired electrical output of approximately 120 volts and 250 watts of power, subgroups of four modules each were assembled and parallel connected with an approximate 30 volts available for each subgroup. Four such subgroups were series-connected to result in a total of 4,480 diode rectifiers or 16 modules assembled in a two foot square self-supporting planar parallel array structure. The individual diode rectifiers connected in each arm of the bridge network are indicated by the numeral **92**. An exemplary module configuration would extend within the area delineated by the dotted lines and reference letter A on one side and similar dotted lines and reference letter B on the other side.

A motor **94** is connected to the DC side of the overall array and may be additionally supported by tubular member **95**. A shaft and propulsion means consisting of rotor blades **97** provide for the upward lift of the overall vehicle for the self-supporting of same in space applications. Additional structural support such as interlaced rigging **96** of a high tensile strength material such as nylon or steel wire, as well as bracing member **98**, may be employed for strengthening of the body means to withstand the vibrational forces and downwash from the propulsion means.

In accordance with the well known technology of microwave transmission the combined array of diode rectifiers and propulsion means presents a specific load impedance which must be suitably matched to the transmitted microwave energy beam to result in maximum efficiency. In aerospace applications a mismatch of approximately ten to one may be evident. Matching of the load impedance to a value of approximately 377 ohms as the free space value will be provided by a plurality of coplanar parallel metallic rod members **99** disposed in a grating array in front of the diode rectifiers a predetermined distance. Rod members **99** are linearly disposed and extend in a similar direction as the assembled diode rectifiers. A selected frontal spacing of one-quarter of the wavelength of the microwave frequency being transmitted has been experimentally determined to be suitable for impedance matching purposes. An approximate spacing of two inches between the respective members was preferred for a selected microwave frequency of 2,450 megacycles. Each of the members **90** are provided with lateral sections **100** to support the elongated bar members **101** which in turn maintain the rod members **99** in the desired position. A tubular member **102** of a lightweight metal may also be provided to combine with the motor support member **95** for structural support.

The combined antenna-rectifier array provides a source of electrical energy to render any space vehicle self-supporting. The diode rectifier elements when assembled in the antenna array have been found to be nondirectional with respect to interception of the beamed microwave energy. This represents a large step forward in the utilization of high power microwave energy over the prior art horn-type receiving antennas which must be accurately focused and pointed in a particular direction for the reception of any energy. The connections between the respective members of the diode rectifier array and deployment in the parallel configuration serves to provide maximum exposed area. Such connections and in particular the end loop portions adjacent the terminus of each arm of the bridge networks serves as an efficient dipole for the interception of the microwave energy.

Although it is not intended as a full explanation of the high degree of efficiency attained with the disclosed antenna-rectifier array, it is believed that the whisker elements within the semiconductor diodes themselves are a contributing factor and may function as additional dipole elements. The disclosed embodiment functioned efficiently when illuminated by microwave energy generating a vertically polarized beam. Hence, an efficient and light weight energy conversion apparatus is disclosed which may be self-supporting without the requirement of a large local fuel supply payload.

It may be within the purview of the invention to use the available rectified electrical energy for performing many functions in addition to the actuation of the propulsion means. Hence, communications' payloads may be maintained at predetermined positions in space in a hovering attitude utilizing a portion of the electrical energy available. Relay signals to other such vehicles or return signals to ground stations would then be within the realm of possibility. Such available energy may also be employed for servomechanisms, stabilizing and countertorque systems for the navigation of such vehicles.

The electrical efficiencies realized with the combined

receiving antenna and rectifier means have also provided certain weight advantages over other energy converters in aerospace applications. Examples of such converters would be heat exchangers or solar cells. In comparison to the present invention where five to eight pounds per kilowatt of energy realized is a normal characteristic, other energy conversion means weigh in the vicinity of 150 pounds per kilowatt of realizable energy. The inherent advantages of the present invention are therefore apparent. While the technology in the diode rectifier art is being continually advanced, new diode power rectifiers as well as integrated circuit techniques are readily available to future configurations of the present invention. The so-called Schottky barrier diodes could be employed to produce combined antenna-rectifier means weighing even less than two pounds per kilowatt of available energy.

Although the foregoing detailed description has referred to DC power rectification it will be evident that with suitable circuit components low frequency AC energy may also be made available. In addition, other propulsion means may be readily substituted using electrical energy. The embodiments disclosed herein are illustrative only and other modifications or alterations will be apparent to those skilled in the art which do not depart from the scope of the broadest aspects of the present invention as defined in the appended claims.

What is claimed is:

1. A space vehicle comprising:

body means;

said body means including spaced structural support members;

combined antenna and DC electrical energy rectification means for the interception and rectification of incident high frequency electromagnetic microwave energy carried by said support members in a planar parallel array;

said rectification means comprising a plurality of four

arm full-wave bridge connected rectifier circuit networks each having a plurality of unidirectional semiconductors in each arm;

said networks being electrically interconnected to common output terminals;

electrically operable propulsion means comprising a motor and rotor members carried by said body means and connected to said terminals for the utilization of said rectified DC energy; and

means for matching the load impedance of said combined antenna and electrical energy rectification means to the incident microwave energy.

2. A space vehicle according to claim 1 wherein said load impedance matching means are arranged in a coplanar array coextensive with said antenna and energy rectification means array, and spaced therefrom a distance of approximately one-quarter of a wavelength at the frequency of the microwave energy.

3. A space vehicle according to claim 2 wherein said load impedance matching means comprise a plurality of parallel disposed elongated metallic members.

TUNNEL DIODE

The invention described herein may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

FIELD OF INVENTION

This invention relates to semiconductor devices and particularly to tunnel diode semiconductor devices.

BACKGROUND OF THE INVENTION

The first tunnel diode was invented by the instant inventor over twenty years ago. Much study and work has gone into improving tunnel diodes but the basic structure has not been altered. The conventional tunnel diode includes a heavily doped p-type material and a heavily doped n-type material. Such heavy doping is required to permit tunneling in narrow junction widths. One result of the heavily doped material was a large number of dislocations in the crystalline structure resulting in high valley currents and attendant power dissipation. A second feature of highly doped tunnel diodes was a substantial tunneling width (length of path) which resulted in a relatively low tunneling current, limiting their high frequency performance.

BRIEF DESCRIPTION OF THE INVENTION

In accordance with the teachings of this invention, an improved tunnel diode is provided with a heterostructure comprising first and second layers of III-V compound semiconductor alloys wherein the first layer is an alloy including a first Group III material and a first Group V material, while the second layer is an alloy including a second Group III material different from the first Group III material and a second Group V material different from the first Group V material, and wherein the valance band of the first alloy is closer to the conduction band of the second alloy than it is to the valance band of the second alloy.

In the preferred embodiment of this invention, the first Group III material is In, the first Group V material is As, the second Group III material is Ga, and the second Group V material is Sb. A further feature of the preferred embodiment is that the first layer is an alloy of $GaSb_{1-y}As_y$ while the second layer is an alloy of $In_{1-x}Ga_xAs$ and y is equal to 0.918x+0.082.

DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the invention, reference should be made to the following detailed description and drawings in which:

FIG. 1 is a schematic drawing showing a semiconductor device including a tunnel diode in accordance with the principles of this invention;

FIG. 2 is an energy level diagram of a conventional tunnel diode;

FIG. 3 is an energy level diagram of a tunnel diode constructed in accordance with the teachings of this invention; and

FIG. 4 is a voltage vs. current diagram of the tunnel diode of FIG. 1.

DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIG. 1 we see a semiconductor device 10 having a first and second ohmic contacts 11 and 12. Connected between the ohmic contacts are layers 13 and 14 which form a junction at their interface 16. A DC power supply 9 in series with a load resistor 8 is connected across semiconductor device 10. An output signal is provided between terminals 6 and 7.

The layer 13 is an alloy including a first Group III material and a first Group V material, while the layer 14 is an alloy including a second Group III material different from the first Group III material and a second Group V material different from the first Group V material. As shown in FIG. 3, the valance band 13V of the layer 13 is closer to the conduction band 14C of the layer 14 than it is to the valance band 14V of the layer 14. Also, as shown in FIG. 3 the layer 13 has been degenerately doped with an excess of acceptors to the extent that the Fermi level lies in the valance band. The layer 14 has been degenerately doped with an excess of donors to the extent that the Fermi level lies in the conduction band. When these layers are interfaced as a heterojunction diode, as shown in FIG. 3, the band edges beyond the junction region are such that the top of the valance band of layer 13 will be higher than the bottom of the conduction band of layer 14, thereby permitting tunnel diode action. In the preferred embodiment, the first Group III material is In, the first Group V material is As, the second Group III material is Ga, and the second Group V material is Sb.

In the preferred embodiment, the layer 13 is an alloy including InAs, and preferably an alloy of $In_{1-x}Ga_xAs$, while the layer 14 is an alloy including GaSb and, preferably an alloy of $GaSb_{1-y}As_y$.

The perameters y and x can be related in a preferred embodiment to obtain perfect lattice matching by the relationship:

$$y=0.918x+0.082$$

The device of FIG. 1 can be manufactured by molecular beam epitaxy. A system useful in growing an alloy semiconductor including the tunnel diode of this invention can be constructed similar to the system described for GaAs and AlAs, by L. L. Chang, L. Esaki, W. E. Howard, R. Ludeke and N. Schul in the Journal, J. Vac. Sci. Technol. 10, 655 (1973) with the exception of its having effusion cells containing elemental sources of the elements In, Ga, Sb and As, and of the dopent Sn. The substrates used include (100) oriented GaAs, InAs or GaSb. Chemically polished substrates should be degreased and etched prior to loading and subsequently Ar+ bombarded and annealed in an ambient of the corresponding group-V element in the molecular beam epitaxy system. The deposition temperature should be between 450° and 600° C., and the growth rate between one and three angstroms per second. The growth rate is determined by the arrival rates of the Group III elements. For a more complete discussion see "$In_{1-x}Ga_xAs$— $GaSb_{1-y}As_y$ Heterojunctions by Molecular Beam Epitaxy, by H. Sakaki, L. L. Chang, R. Ludeke, C. A. Chang, G. A. Sai-Halasz and L. Esaki; Appl. Phys. Lett. 31, 211 (1977), and MBE of InGaAs and GaSbAs, by C. A. Chang, R. Ludeke, L. Chang, and L. Esaki, Appl. Phys. Lett. 31, 759 (1977).

A comparison of FIG. 2 to FIG. 3 will show that the energy level diagram of FIG. 3 (of the tunnel diode of this invention) closely resembles the energy diagram of known tunnel diodes produced by heavy doping. It is noted that the differences between FIG. 2 and FIG. 3 can be viewed as though the shaded portion indicated as d in FIG. 2 has been removed and the remaining portions have been brought closer together. This results in a shorter tunneling path and therefore higher current in the structure of the present invention. A further advantage of the present invention is improved crystallinity resulting from the lower doping which produces a lower valley current than in conventional tunnel diodes. The net effect is a tunnel diode having a characteristic such as shown in FIG. 4 wherein the peak current is enhanced and the valley current is substantially reduced from conventional tunnel diodes providing better high frequency performance.

While this invention has been described with respect to particular embodiments thereof, numerous others will become obvious to those of ordinary skill in the art in light hereof.

What is claimed is:

1. A tunnel diode comprising: first and second layers of different semiconductor materials; the top of the valance band for the material of said first layer being at an energy between the energy of the bottom of the conduction band and the top of the valance band for the material of said second layer; the bottom of the conduction band for the material of said first layer being at an energy greater than the energy of the bottom of the conduction band for the material of said second layer; said first layer being degenerately doped with an excess of acceptors to the extent that the Fermi level lies in the valance band; said second layer being degenerately doped with an excess of donors to the extent that the Fermi level lies in the conduction band; and said first and second layers being interfaced to form a semiconductor heterojunction.

2. A tunnel diode according to claim 1, wherein the top of the valance band of said first layer is closer to the bottom of the conduction band of said second layer than it is to the top of the valance band of said second layer.

3. A tunnel diode as defined in claim 1, in which said layers are formed from different Group III-V alloys.

4. A tunnel diode as defined in claim 2, in which the first layer is an alloy of $In_{1-x}Ga_xAs$ and the second layer is an alloy of $GaSb_{1-y}As_y$,

5. A tunnel diode as defined in claim 4, in which $y=0.918x+0.082$.

[57] **ABSTRACT**

A method and system are described for transmitting electromagnetic radiation by using a communications mirror located between about 100 kilometers and about 200 kilometers above ground. The communications mirror is kept aloft above the atmosphere by the pressure of the electromagnetic radiation which it reflects, and which is beamed at the communications mirror by a suitably constructed transmitting antenna on the ground. The communications mirror will reflect communications, such as radio, radar, or television waves up to about 1,100 kilometers away when the communications mirror is located at a height of about 100 kilometers.

COMMUNICATIONS SYSTEM USING A MIRROR KEPT IN OUTER SPACE BY ELECTROMAGNETIC RADIATION PRESSURE

This invention was made in the course of, or under, a contract with the Department of Energy.

BACKGROUND OF THE INVENTION

This invention relates to a communications system using an electromagnetic energy reflector or mirror kept in outer space by electromagnetic radiation pressure.

Good non-cable television reception generally requires line-of-sight transmission. To increase line-of-sight range, a television broadcasting station can increase the height of its transmission antenna. However, due to construction costs, weight, wind, and other factors, the height of a television antenna is limited. One method to increase the line-of-sight range of television reception is to locate relay stations to receive television signals by a long cable or line-of-sight transmission from a television broadcasting station and then to rebroadcast the signals to television sets in the vicinity of the relay station.

To extend the range of television reception the reflector mirror could be attached to an earth satellite. However, an earth satellite would, in general, move with respect to the surface of the earth and stay above the horizon only for a few minutes at a time (approximately less than 10 minutes when the height is approximately less than 600 kilometers). That, together with the expensive cost of satellite launching, makes this an unattractive possibility. Earth satellites, whether stationary or not, do not require energy transmitted from the earth to stay in orbit.

A stationary earth satellite equipped with a large reflector communications mirror would serve the desired purpose. Given sufficient power, it could beam programs to viewers located almost anywhere on about one-half of the earth's total surface. For such a satellite, the height is necessarily about 36,000 kilometers. If the wavelength equals 2 meters and the antenna's radius equals 1.2 kilometers, then the radius of the reflector communications mirror must be greater than approximately 36 kilometers. A mirror of this size would have to be assembled in orbit.

Expensive and sophisticated equipment is required to receive signals from existing communication satellites. Presently these reflected or retransmitted signals are eventually received by TV relay stations to be rebroadcast along line-of-sight to TV sets in the vicinity. Such satellites operate above the earth's ionosphere where ionospheric interference with signal transmission from and to the earth is found. Such satellites operate with decreased transmission efficiency because of the great distances involved. Thus even with satellites, most television viewers today are able to receive only programs beamed to them from a relay station located nearby. In those areas where there are no relay stations, or where existing stations do not transmit programs which some viewers wish to receive, good reception of desired programs is usually impossible. These difficulties could be avoided only if the need for local relay stations could be eliminated. There is also presently lacking an effective means for over-the-horizon radar and a means to impart a high electromagnetic radiation intensity to a wide area on the ground.

SUMMARY OF INVENTION

In view of the above, it is an object of this invention to provide line-of-sight electromagnetic wave transmission to areas lacking line-of-sight broadcasting or ground relay stations.

It is a further object of this invention to provide over-the-horizon electromagnetic wave transmission without the use of earth orbiting satellites or long cables.

It is a further object of this invention to provide for a transmission system to cover large areas of the earth with lower cost, lower power, and higher transmission efficiency than that of earth orbiting satellites.

It is a further object of this invention to provide television reception over large areas of the earth essentially without ionospheric interference with signal transmission.

It is a further object of this invention to provide for over-the-horizon radar and a means to impart a high electromagnetic radiation intensity to a wide area on the ground.

Various other objects and advantages will appear from the following description of an embodiment of the invention, and the most novel features will be particularly pointed out hereinafter in connection with the appended claims. It will be understood that various changes in the details, materials, and arrangements of the parts which are herein described and illustrated in order to explain the nature of this invention may be made by those skilled in the art without departing from the scope of the invention.

The invention comprises a method and system for transmitting electromagnetic radiation comprising disposing an antenna on the earth, transmitting electromagnetic radiation, having a diffraction peak and interference pattern, from said antenna generally vertically upward, disposing a dish shaped electromagnetic radiation reflector communications mirror, having a center of mass located below the point of attack of said transmitted electromagnetic radiation, at a height from about 100 kilometers to about 200 kilometers generally vertically above and oriented face down towards said antenna, supporting said mirror's weight by the electromagnetic radiation force transmitted by said antenna, controlling the height of said mirror by varying the intensity of said force, and reflecting said electromagnetic radiation or some other electromagnetic radiation with said mirror back toward the earth.

DESCRIPTION OF DRAWING

The present invention is illustrated in the accompanying drawing wherein:

FIG. 1 is a diagrammatic view of a communications system showing the signal transmission path and apparatus of the communications system embodying this invention;

FIG. 2 is a diagrammatic and perspective view of the reflector communications mirror;

FIG. 3 is a diagrammatic and perspective view of a multiple mirror system;

FIG. 4 is a diagrammatic view of a ground antenna arrangement or array composed of constituent antennas;

FIG. 5 is a diagrammatic view of a multiple antenna system for communication between different parts of the earth; and

FIG. 6 is a diagrammatic view of an over-the-horizon radar system.

DETAILED DESCRIPTION

In the following "television wave" shall mean an electromagnetic wave in the television or microwave range. In FIG. **1** a television transmitting antenna or antenna array **10** is located on the earth **12**. Television broadcasting equipment **13** transmits by the antenna **10** a television wave **14** vertically upward. Directly above the antenna **10** is a television wave reflector communications mirror or mirror system **16** at a height H above the earth's surface. The reflector mirror **16** reflects the transmitted wave **14** as a reflected wave **18** along a line of sight to the antenna of a home television set **20**, which is located at a distance L from the transmitting antenna **10**. The television set may be close to or over the horizon from the transmitting antenna. An obstacle **22** such as mountains may be between the television set and the transmitting antenna.

If the reflector mirror **16** is located at a height H of 100 kilometers above the earth **12** it will be in direct view of any viewer on the earth **12** within a distance L of about 1,100 kilometers as measured from the transmitting antenna **10**. Therefore, it would beam programs directly to the viewers. If the transmitting antenna **10** radiated approximately 10 or more megawatts of power **14**, then the reflected signal **18** would be strong enough to get behind most of the common obstacles, such as tall buildings, and thus ensure good reception almost anywhere within about 1,100 kilometers of the transmitting antenna **10**. In general, a reflector communications mirror located at height H above the earth **12**, would be above the horizon when viewed from within a circle of radius $L \approx (2HR_E)^{\frac{1}{2}}$, where R_E is the radius of the earth, provided that $L << R_E$.

With a transmitting antenna **10** of radius r_g located on the ground, and a reflector communications mirror **16** of radius r_a located at a height H above the ground, at least 84 percent of the power radiated by the transmitting antenna **10** will reach the reflector communications mirror **16** (all the power radiated into the first Fresnel Zone) provided that

$$r_a \gtrsim 0.6\lambda h/r_g \qquad \text{(Equation 1)}$$

where λ is the television carrier wavelength, and the reflector communications mirror is located at a height H above ground. For H=100 kilometers, λ=1 centimeter, and $r_g=300$ meters, a reflector communications mirror with a radius $r_a \gtrsim 2$ meters is needed, as derived from Equation 1.

The reflector communications mirror **16** may be made to reflect TV waves not to a relay station, but directly to those areas on the ground where the programs are to be viewed. A wide range of frequencies may be so reflected, no "tuning" of the reflector communications mirror **16** is necessary.

The reflector communications mirror **16** of radius r_a may be maintained at a height H solely by the radiation pressure **14** exerted on it by the electromagnetic waves which it reflects. A satellite is not needed to carry it. The equipment **13** may include means to sense variations in height of the mirror **16** and to adjust the power of radiation transmitted to control the height of the mirror **16**.

At normal incidence, 10 magawatts of radiation will exert a force of about 6.67 gram weight on a totally reflecting perfectly flat mirror. Real communication mirrors are neither perfectly reflecting, nor perfectly smooth. Nevertheless, for wavelengths of interest, deviations from the ideal case can be made relatively small, so that if the mirror weighs 6.67 grams, it will "float" on the radiation **14** impinging on it, whenever the radiation carries somewhat more than 10 megawatts of power.

When the mirror is located at or above 100 kilometers, it will be above most of the atmosphere. At this height the wind pressure on it is negligible. There are only two dominant forces acting on it: radiation pressure and gravitation. The mirror needs no rigid frame: the interplay of these two forces will "blow up" the mirror to its desired (for example, parabolic or shallow dish) shape, just as gravitation and wind pressure are known to blow up a parachute.

The communications mirror will be made light enough to float on the radiation it reflects. The mirror may consist of a set of parallel wires with a diameter 2r, located at a distance d from each other. When the wires are parallel to the electric field in the impinging wave, the transmissivity of such a mirror is

$$T \approx 4(d/\lambda)^2\{\ln|[0.83\exp(2\pi r/d)][\exp(2\pi r/d)-1]^{-1}|\}^2 \qquad \text{(Equation 2)}$$

A similar formula is given in N. Marcuvitz, *Waveguide Handbook* (Maple Press Co., York, Pa., 1951).

For λ=2 meters, d=5 centimeters, $2r=10^{-3}$ centimeters, Equation 2 gives a transmissivity T of 12.9%.

The wires will absorb some of the radiation falling on them. This energy will heat the wires. However, the heating will not melt the wires. A good conductor will absorb a fraction A of the energy impinging on its surface, where

$$A = c(\pi\sigma\delta)^{-1}2d^2/\pi^2 4r^2 \qquad \text{(Equation 3)}$$

Here σ is the conductivity of the conductor, c is the speed of light, and for wavelength λ, the skin depth is $\delta \approx (2\pi)^{-1}(c\lambda/\mu\sigma)^{\frac{1}{2}}$ where μ is the magnetic permeability. When $d/\lambda << 1$ then the mirror can be thought of as an approximately smooth surface in which a spatially uniform surface current is ocillating. The oscillations must cancel (1−T) fraction of the field energy behind the mirror. In reality, of course, the current is confined to the wires. However, if d/λ is small enough, the approximation will be a good one. In this approximation, the energy absorbed by the mirror is A times the energy reflected from the mirror.

A mirror made of a set of parallel wires would work. Nevertheless, it is often better to have a mirror made of two perpendicular sets of parallel wires in a checkerboard array, every wire in the first set being perpendicular to every wire in the second set, and all wires lying in the surface of the mirror **16** as shown in FIG. **2**. Each set contains the same number of wires and the spacing d between wires **24** in both sets is the same. In other words, we have a mirror **16** made of a wire mesh (like a screen) instead of a set of parallel wires. Such a mirror can better withstand mechanical stresses, and a rotation of the mirror (with respect to the incoming electric field **14**) can be ignored, as long as the surface of the mirror is left unchanged. As an example of such a mirror, consider a circular plane wire mesh with a mirror radius r_a as in FIG. **2**. The total length of the wires needed to make the mesh, when $d << r_a$, is $S \approx \pi r_a^2(d^{-2})2d$, so that total weight of mirror is

$$F_g = \pi r^2(2\pi r_a^2 d^{-1})\rho \qquad \text{(Equation 4)}$$

where β is the specific weight of the wire material. When ($\lambda=1$ centimeter) $d=7.66\times10^{-2}$ centimeters, $2r=10^{-4}$ centimeters, $r_a=2$ meters, and the wire material is aluminum, then $\rho=2.70$ gram/cubic centimeter, $S\approx3.2\times10^{6}$ centimeters, and $F_g=6.95\times10^{-2}$ grams. Thus the entire mirror can be supported by the pressure of 100 kilowatts radiation reflected from the mirror.

The total surface of all the wires in the mesh is B. If the mesh has temperature t, and is placed in outer space, then the power radiated by it is given by the Stefan-Boltzmann law:

$$W_t=(\epsilon)5.67\times10^{-12}\,(\text{Watts deg}^{-4}\,\text{cm}^{-2})t^4(B) \qquad \text{(Equation 5)}$$

Where ϵ is the emissivity of the wires surface. For copper, $\epsilon\approx0.15$ (somewhat higher for oxidized surface). If necessary, one can always increase the density of wires in the mirror (i.e., decreased). This will increase the weight of a unit mirror surface. Alternatively, one can reduce the wire radius, and if $2r\lesssim\delta$, use a multiple mirror system consisting of several mirrors located one above the other (see below). Yet another possibility is to use ribbon shaped wires rather than wires with circular cross section. If the thickness of the ribbons $\lesssim\delta$, one can lay a circular wire with $2r\gtrsim\delta$ on each ribbon to increase the mirror reflectivity.

The tensile strength of an aluminum wire is about 1.1×10^{6} grams/square centimeter. Thus an aluminum wire with $2r=10^{-4}$ cm can carry 8.64×10^{-3} gram weight, or 12% of the total mirror weight. Since there are now over ten thousand wires in this mesh, there will be no overstressing of the wires. Even if one-half of the mirror were to be pulled in one direction by some unforeseen force ten times as large as the weight of this half-mirror, and the other half pulled in the opposite direction by a force of equal magnitude the wires would on the average still carry less than 0.15% of the tensile strength. Since, furthermore, the wires are elastic, averaging is expected.

Meteors are not likely to be a major problem. The total area presented to a meteor by the mirror is $S\times2r$. For the parameter values chosen above, that means only $\approx3.2\times10^{-2}$ square meters. Should a meteor nevertheless strike a wire, the wire will break at the point of impact, unless the force along the wire is less than 8.64×10^{-3} gram weight. Only a small component of which will be perpendicular to the mirror surface. On the other hand, even a force of 8.64×10^{-3} gram weight is much less than the weight of the mirror, and can be counterbalanced by a small fractional temporary increase in the power radiated from the ground.

When the parameters are chosen as above ($H=10^{5}$ meters, $\lambda=1$ centimeter, $r_a=2$ meters) then Eq (1) would require that $r_g\gtrsim300$ meters. The value of r_g can be kept small in the following way.

Instead of placing a single mirror to a height H above ground, several parallel mirrors are placed there, one behind the other at a distance b from each other. This is shown in FIG. **3** for three mirrors: **16**$_a$, **16**$_b$ and **16**$_c$. This is particularly useful, if a large B value is desired, or when the wire diameter 2r is less than the skin depth δ for the radiation impinging on the mirror. As an illustration, suppose that $\delta/r=n$ which is >1. When $n>>1$, then a single mirror of the above type will transmit most of the radiation impinging on it, even if according to Equation 2, the transmissivity of the mirror would be small. The reason is that in equations like Equation 2, the wires are assumed to be perfect conductors, i.e., one approximates the correct result by putting $\delta=0$. This approximation is a good one only as long as $\delta<<2r$. When $\delta\gtrsim2r$, the radiation leaking through the wires becomes significant, and the transmission increases. To reduce this transmission, one may increase r. If that is done, the weight of the mirror will increase proportionally to r^2. By contrast—and this is what is suggested here—one may leave the wire radii unchanged, but place several mirrors of similar construction one above the other. Now each individual mirror will still have a large transmissivity, but when the number of mirrors, n, is such that $n\gtrsim\delta/2r$, then the transmissivity of the mirror system as a whole can be made small. The total weight of the whole mirror system is roughly proportional to n (exactly so if all mirrors are identical). This is to be compared with the previously mentioned case where the total weight was proportional to r^2 which in turn is proportional to n^2.

In practice the mirrors should be made similar, but not identical to each other: since less radiation reaches the higher lying mirrors, their reflection efficiency per unit weight has to be made higher than for the lower lying mirrors of the mirror system.

The wires may be deposited on thin threads of some light high-strength material such as a polyester resin material; for example a polyester of ethylene, glycol and terephthalic acid. Such materials may exhibit a specific weight considerably less than that of copper.

The ground antenna may be a sequence of parallel conductors, appropriately phased, to imitate a paraboloid. If the distance between adjacent wires is λ, then although the near field of the antenna will differ from that of a smooth paraboloid, the far field will not.

The mirror may be shaped so as to be stable with respect to horizontal drifting and tilting. If the mirror has the shape of a dish, facing down, then it will be stable with respect to horizontal displacements away from the center of the diffraction peak created by the transmitting antenna on the ground. The mirror could be circular, generally elliptical, or any other suitable configuration. If the mirror is displaced, e.g. to the left, the force exerted on its right side by the radiation will exceed that exerted on its left side. This force will have a horizontal component, pushing the dish back to the center. Possible oscillations will be damped by the rare atmosphere around the mirror. Should higher damping be desired, the mirror may be lowered temporarily, by decreasing antenna power, to denser atmosphere at times when the wind there is moderate. Slowly displacing the axis of the interference pattern created by the ground antenna, will, by the same argument, induce a corresponding displacement of the floating mirror. Thus, its lateral as well as vertical position could be controlled from the ground. Stability against tilting can be insured by arranging the center of mass of the mirror to lie below the point of attack of the resultant lift force. This may be achieved by making the perimeter of the dish heavier than its center, or, better yet, by hanging a small weight from its periphery in a manner of a weight hanging from a parchute. In either case, the radiation will "blow up" the mirror to its desired shape, and will keep it facing down. The radii of curvature of the dish will determine the shape of the area in which it will radiate. There is no need to make all radii equal: the perimeter of the dish may be e.g. an ellipsoid. Usually, smaller radius of curvature will mean larger area illuminated.

The mirror shape and effective radius can be varied by rotating the mirror around its axis at various angular velocities. The angular velocity can be governed from the ground by rotating the plane of polarization of the radiation impinging on the mirror. For example, flaps could be hung from the edge or perimeter of the mirror which would gradually open up as the angular velocity increases.

While reference is made to the antenna **10** being located "on the earth," one can readily appreciate that it could be supported by a tower, airplane, ship, or the like.

The electromagnetic radiation transmitted by the antenna **10** could include microwaves, radar, television, short wave radio, medium wave radio, and long wave radio transmissions, as well as radiation of shorter wavelength such as visible light. The wavelength of the electromagnetic radiation signal that is being transmitted by mirror **16** will be effected by the spacing between the wires of mirror **16** and possibly their diameters.

The reflector mirror would be disposed at a height below about 36,000 kilometers which is the height of a stationary earth orbiting satelite. Below about 36,000 kilometers radiation force is needed to support the reflector mirror. The preferred height is about 200 kilometers for size and power considerations.

The antenna **10** may be a circular dish ground antenna. However, in many cases it is desirable to use not a circular dish ground antenna, but rather an array of smaller "constituent" dish antennas (items $\mathbf{10}_a$, $\mathbf{10}_b$, $\mathbf{10}_c$ etc., as shown in FIG. **4**) placed next to each other along two straight axes on the ground arranged in a cross shape. Additional constituent antennas may be placed between the lines as shown in FIG. **4**. The constituent antennas need not all be circular nor of the same size. Furthermore, for many applications it is desirable to have the radiation intensity emitted by the smaller constituent antennas vary for example as a Gaussian, as a function of the location of the constituent antennas; in an xy cartesian coordinate system, the center position of any constituent antenna would be denoted as (x,y). The intensity of that constituent antenna is then given by the product of two gaussians, one as a function of x with width σ_x the other as a function of y with width σ_y (σ_x may be choosen to be equal to σ_y).

In some cases it may be desirable to have a ground antenna system consisting of several antennas (with each antenna consisting of one or more constituent antennas) located at large distances (comparable to H) from each other. FIG. **5** shows a three antenna **10**, $\mathbf{11}_a$, and $\mathbf{11}_b$ system. Such arrangement will allow greater flexibility in choosing the final position of the mirror by varying the intensity of the electromagnetic radiation radiated by each antenna.

In FIG. **5**, each antenna **10**, $\mathbf{11}_a$, and $\mathbf{11}_b$ does not have to transmit electromagnetic radiation of the same wavelength. Thus several television channels of information may be transmitted. A reflector communications mirror **16** may be designed such that certain parts or segments of the mirror would reflect electromagnetic radiation of certain wavelengths better than other wavelengths. For example, a mirror may be constructed with three corners such that each corner would reflect microwaves best and the center of the mirror would reflect longer wavelengths best. Also, referring to FIG. **4**, each constituent antenna such as $\mathbf{10}_a$ may transmit at several different frequencies. Referring to FIG. **5**, the intensity of the transmitted radiation from each of the three antennas **10**, $\mathbf{11}_a$, and $\mathbf{11}_b$ may be chosen such that the three antennas act not only to transmit electromagnetic radiation to a desired point **20** but also to support the mirror **16**. As an option, the intensity of the electromagnetic radiation of the antenna **10** directly underneath the mirror **16**, in FIG. **5**, may be chosen to be much greater than the intensity of the other two antennas, $\mathbf{11}_a$ and $\mathbf{11}_b$. Thus the electromagnetic radiation from the antenna directly underneath the mirror would be used mainly to support the mirror while the desired information signals would come from the other antennas, to be reflected by the mirror **16** to the desired point **20**.

An over the horizon radar system is depicted in FIG. **6**. In this system the reflector mirror **16** is supported solely by antenna **10**. The electromagnetic radiation **14** from the antenna **10** is much larger than any other radiation impinging on the mirror **16**. An airplane **26** emits a radar signal along path **28** which is reflected by mirror **16**, and the reflected signal along path **30** strikes a target **32**. The radar wave is reflected by the target **32** along path **30** to again strike mirror **16** to be finally reflected back along path **28** to a receiving station located on the airplane **26**. Of course it is to be understood that the radar signal could be emitted and received from a point near antenna **10**.

The reflector mirror may be kept afloat by radiation pressure at altitudes lower than where satilites are generally located. In particular, it may be kept below most of the ionosphere, so that the ionosphere's interference with signal transmission may be essentially eliminated. Close proximity to the earth allows higher transmission efficiency from the earth to the mirror and back.

If the ground antenna emits high enough radiation and if the communications mirror is large enough, radiation intensity reflected from the mirror may reach dangerous levels on the ground. If that is not desired, the danger may be eliminated by restricting the mirror's radius. Thus the mirror may be made perfectly safe. Actually, the radiation from a properly designed mirror will be environmentally even safer than the radiation emited by the large number of relay stations now in use. The near fields of the existing relay stations may be dangerous, whereas the near field of the communications mirror is located far from all human habitat and is thus harmless. On the other hand, the far field of the mirror may be designed to assume essentially the most desired value on the ground.

For launching the mirror, it may be placed on a frame or in a container while being lifted by a balloon or series of balloons through the lowest layers of the atmosphere. This will provide protection from the forces due to wind. As the balloon rises, air density decreases and, consequently, so does the force exerted by the wind on the mirror (or its container). At some height (part of) the frame or container can be released and the remaining lighter load raised further. The frame or container may be released in several stages. Eventually, the mirror is released and final positioning is done by varying the radiation pressure from the ground.

What we claim is:

1. A method for transmitting electromagnetic radiation signals comprising transmitting electromagnetic radiation, having a diffraction peak and interference pattern, from an antenna located on the earth generally vertically upward; disposing a dish shaped electromagnetic radiation reflector communications mirror, having a center of mass located below the point of attack of said transmitted electromagnetic radiation, at a height of from about 100 kilometers to about 200 kilometers generally vertically above and oriented face down towards said antenna so as to receive said transmitted electromagnetic radiation; supporting said mirror by the force produced by said electromagnetic radiation transmitted by said antenna; controlling the height of said mirror by varying the intensity of said force; and reflecting electromagnetic radiation signals with said mirror back toward the earth.

2. The method of claim 1 wherein said electromagnetic radiation signals have a wavelength from about that of microwaves to that of radio waves.

3. The method of claim 1 wherein said mirror reflects said electromagnetic radiation signals back towards the earth over the horizon from said antenna.

4. The method of claim 1 further including disposing an array of said antennas on earth configured so that the resultant total electromagnetic radiation is transmitted generally vertically upward, and disposing said mirror generally vertically above said resultant total electromagnetic radiation.

5. The method of claim 4 wherein one or more antennas are transmitting at different wavelengths.

6. The method of claim 1 further including disposing a plurality of said mirrors vertically positioned at different heights.

7. The method of claim 1 further including adjusting the lateral position of said mirror by displacing the axis of the interference pattern created by said antenna's electromagnetic radiation.

8. The method of claim 1 wherein said electromagnetic radiation includes plane-polarization and further including disposing a plurality of flaps on the edge of said mirror and rotating the plane of polarization of said radiation to rotate said mirror to open up said flaps to change the shape and effective radius of said mirror.

9. A system for transmitting electromagnetic radiation signals comprising an antenna means disposed on the earth for generally vertically transmitting electromagnetic radiation having a diffraction peak and interference pattern; means for generating electromagnetic radiation and transmitting the same through said antenna; means for varying the intensity of said electromagnetic radiation; and a dish shaped electromagnetic radiation reflector communications mirror, having a center of mass located below the point of attack of said transmitted electromagnetic radiation, at a height, of from about 100 kilometers to about 200 kilometers generally vertically above and oriented face down towards said antenna, at which said mirror's weight is supported by the transmitted electromagnetic radiation force from said antenna, to effect reflection of said electromagnetic radiation signals with said mirror back towards the earth.

10. The system of claim 9 wherein said electromagnetic radiation signals have a wavelength from about that of microwaves to that of radio waves.

11. The system of claim 9 wherein said mirror comprises two generally perpendicular sets of generally equally spaced parallel wires having a checkerboard array.

12. The system of claim 12 wherein the wires of said mirror are of generally circular cross section having diameters substantially smaller than the spacing between said generally parallel wires.

13. The system of claim 9 wherein said antenna means includes an array of antennas wherein said array is positioned to provide generally vertically upward resultant electromagnetic radiation, wherein said mirror is generally vertically above said electromagnetic radiation.

14. The system of claim 13 wherein said antennas of said array transmit said electromagnetic radiation at different radiation wavelengths.

15. The system of claim 13 wherein said mirror compromises a plurality of mirrors wherein said mirrors are disposed at different lateral positions generally vertically above said array of antennas.

16. The system of claim 9 further including a plurality of said mirrors with all mirrors positioned at a different height generally vertically above said antenna means.

17. The system of claim 9 further including a separate radar apparatus, having substantially less power than said antenna means, to effect the detection of an over-the-horizon target with said mirror.

18. The system of claim 9 wherein said electromagnetic radiation includes plane-polarization and further including a plurality of flaps depending from said mirror and means for rotating the plane of polarization of said radiation to effect the rotation of said mirror to effect the opening up of said flaps to effect the change of the shape and effective radius of said mirror.

[57] ABSTRACT

In an interferometric apparatus the path of the output beam of a rotary Optical Path Difference scanning assembly leading to an electrically responsive detector is maintained substantially fixed in space for any scan angle within predetermined limits, thus obviating a serious drawback of a prior art proposal wherein the output beam translates significantly over the detector face with changes in scan angle, with the result that the detector output is vitiated by totally spurious variations of the energy reaching it.

In one embodiment, the scanning assembly comprises a beam splitter having a semi-reflective layer the output face of which cooperates with the face of an output mirror normal thereto, the axis of rotation being substantially coincident with the line of intersection between the prolongation planes of the two faces. A Fourier Transform spectrophotometer embodying the assembly is also described.

INTERFEROMETRIC OPTICAL PATH DIFFERENCE SCANNERS AND FT SPECTROPHOTOMETERS INCORPORATING THEM

BACKGROUND OF THE INVENTION

This invention relates to interferometric apparatus comprising a rotary scanner of the optical path difference between two optical paths, such as the two arms of an interferometer of the Michelson type, in particular a Michelson interferometer forming part of a Fourier Transform Spectrophotometer, the rotary scanner being such as to enable the beam outputted therefrom to remain substantially fixed in space for any angle of rotation within predetermined scanning limits.

It is believed that, although the phrase "optical path difference" and the related phrases "optical path length" and "geometrical path length" presently to be encountered are well understood in the interferometric art, it would be of assistance to the reader in appreciating their significance in the present context if they were distinguished from the outset.

We will distinguish first the phrases "geometric path length" and "optical path length", in which the path referred to is that followed by light rays between two points spaced along their travel or, more specifically, two spaced optical elements. The "geometrical path length" is simply the length, in any convenient units of linear measure, of the path through air, or any other medium, from one to other of said points. The "optical path length", on the other hand, takes into account the retardation effect on light waves of any intervening medium other than air. By definition, it is the product of the geometrical path length and the refractive index of the medium. The refractive index (usually denoted by the letter n) is in fact a measure of the retardation. If a light wave takes a time t to travel between two spaced points in air, it will take a time $t \times n$ to travel between the same two points when a medium of index n greater than 1 is substituted. If $n=2$, for example, the travel time is doubled.

It will be appreciated, therefore, that two light waves initially travelling in phase coincidence along two separate paths of the same geometrical path length (if no media other than air are included in the paths) or optical path length (if media other than air are present) are thrown out of step if one is retarded with respect to the other by increasing the geometrical path length or the optical path length, as the case may be, of one path with respect to the other.

A system of mirrors can clearly be used to change the geometrical path length simply by increasing or decreasing the distance travelled in air by the light rays. It follows that even where refractive elements are present the system will still alter the geometrical length of that portion of the overall path that passes through air and, therefore, it will alter the optical path length, in so far as the latter is derived from the former in the manner hereinbefore referred to.

Two optical paths may have the same geometrical path length and yet one path will cause greater retardation than the other if its optical path length is greater. On the other hand, equality of optical path lengths is always associated with equal retardations. This means that the phrase "optical path length" has greater generality and may conveniently be used in a context where refractive elements may or may not be involved.

As to the phrase "optical path difference", it simply relates to the difference in optical path length between two paths that may include media other than air. The phrase "geometrical path difference" is not often used, but after what has been said in the preceding paragraph, its meaning should be clear.

In the present context, the phrases "optical path length" and "optical path difference" (hereinafter frequently referred to and conveniently denoted by the initials O.P.D.) are intended to be associated with situations where the presence of media other than air is not to be excluded but not necessarily included.

In a basic Michelson-type interferometer, the radiation flux emanating from a source of monochromatic light, either in the visible or the invisible regions of the electromagnetic spectrum, impinges on a beam splitter after passing through a collimator. The beam splitter is oriented at an angle of 45 degrees to the direction of the incoming collimated beam so that a portion (i.e. percentage) of the impinging beam is transmitted without change of direction and a portion is reflected through a 90-degree angle. Each portion is reflected back towards the beam splitter by a beam reversing mirror, the return optical path being coincident with the forward path. At the beam splitter recombination of the two portions takes place, with the first now progressing in reflection and the second in transmission towards a common path leading to a light receiving device, which may be a screen or a photoelectric detector.

Now, if the optical path length between the beam splitter and one reversing mirror, which together represent one arm of the interferometer, is made identical with that between the beam splitter and the other reversing mirror, which together represent the other arm of the interferometer, the reflected and transmitted beams will suffer no relative phase changes and consequently will recombine at the beam splitter so as to be indistinguishable—if transmission losses and optical imperfections are notionally assumed to be zero and the beam splitter provides 50% reflection—from the unsplit optical beam.

If, on the other hand, an optical path difference that is significant compared with one half wavelength of the monochromatic light is established between the two arms of the interferometer, such as by moving one of the reversing mirrors towards the beam splitter, interference effects may be expected. The frequency of the resultant sine wave representing the recombined beam will be the same as that of the two constituent sine waves representing the beams prior to their recombination. The amplitude, on the other hand, will be the algebraic sum of the constituent sine waves amplitudes at each successive abscissa point and therefore will vary sinusoidally from a maximum, when the optical path difference is equal to an integral number of wavelengths, and, therefore, the amplitudes of the constituent waves add up (constructive interference), to a minimum, when the optical path difference is equal to an integral number of wavelengths plus one half wavelength and the waves are therefore in phase opposition so that the amplitudes subtract (destructive interference). A series of concentric rings (called interference fringes), representing the maxima and minima of the resultant sine wave, and therefore alternately bright and dark, may be viewed by interposing an ordinary white diffusing screen at the focus of a converging lens interposed in the path of the recombined beam, provided the monochromatic source radiates visible light.

Alternatively and more usefully, the optics of the interferometer may be arranged to project an image of the aperture stop (also called Jacquinot stop) of the interferometer at a photodetector having a circular window for admitting the central interference fringe (i.e. the first ring). This fringe will change from a light to a dark patch as the optical path difference undergoes a change equal to one half wavelength through the movable mirror being displaced between positions corresponding to constructive interference and destructive interference, respectively. The sinusoidal electrical output of the detector can be processed to provide an accurate linear measurement of the mirror displacement and, therefore, of any member suitably mechanically coupled to the mirror, to within a small fraction of one half wavelength. Displacements of exact half wavelengths can, of course, be measured by counting the mean level crossings of the output signal from an appropriate datum. Each crossing counted from the datum represents a change of O.P.D. of exactly half the wavelength of the source, i.e. a displacement of the member of exactly ¼ wavelength. When a monochromatic source is used the wavelength of which is known precisely, interferometric measurements of length as suggested are perhaps the most sensitive and accurate available to man.

A field of application predicted by Michelson for his interferometer, but only of comparatively recent application, is Fourier Transform spectroscopy (hereinafter FT stands for Fourier Transform). If the movable mirror referred to earlier is actually displaced between a position corresponding to zero O.P.D. and a predetermined limit by mounting the mirror on an accurate scanning assembly following a strictly rectilinear path, the output of the photo-detector will be a sine wave of much lower frequency compared with the monochromatic emission line of the source but constant peak-to-peak amplitude. If it is assumed that the wavelength of the optical input to the detector is, say, 2.5 micrometers and the predetermined limit of the optical path difference is 2 cm then clearly the number of recurrent cycles in the detector output must be 2 cm/0.00025 cm=8000. If the time taken to move the mirror between zero optical path difference and the limit is 1 second, then the frequency of the detector output signal is 8000 Hz. In other words, the original optical wave has been modulated at a frequency of 8000 Hz, well within the audio range. The modulation sine wave, which may be displayed on a CRT, represents the interferogram of the source. If the Fourier Transform of the interferogram is computed, the resulting trace, in the form of a very narrow band, represents the emission line spectrum of the source.

If a broad-band source, e.g. an infrared source, is substituted for the monochromatic source, the output of the detector when the scanning mirror is in motion will no longer be a pure sine wave since the emission spectrum of the source will include waves of different frequencies. Each of the optical sine waves will give rise to two constituent beams and one resultant beam in the manner described earlier and all the resultant beams of different frequencies will be represented in the instantaneous output of the detector, each by its own modulation sine wave of related frequency and amplitude. If the output of the detector is plotted as before, the trace that results represents the emission interferogram of the source.

Now, if a sample not opaque to infrared is placed at the Jacquinot stop, the waves of different frequencies present in the emission spectrum of the source are attenuated to a different extent in a manner that is characteristic of the chemical nature of the sample and the resulting interferogram represents the infrared absorption interferogram of the sample superimposed on the emission interferogram of the source.

By taking the Fourier Transforms of the two interferograms, thus obtaining independently the spectrum of the sample-cum-source and that of the source alone, and then ratioing the first spectrum by the second, the spectrum of the sample is derived. In general the interferogram will consist of a dominant centreband flanked by intermingled waves decrementing more or less symmetrically in amplitude to vanishing values. It is worth observing that there is no point of communality between the various sine waves other than at the position of the scanning mirror corresponding to zero O.P.D. where all waves will undergo constructive interference; and that, of course, is the reason for the presence of the dominant centreband.

It can now be readily appreciated that, whatever the application of the Michelson-type interferometer which necessitates the optical path difference between the two interferometric arms to be changed, a very serious mechanical problem arises.

If mechanical imperfections in the guideways cause the moving mirror to tilt during the scan motion, the effective optical path difference may not be the same for each of several parts of the beam traversing different regions of the beam splitter, with the result that for a given wavelength some parts may be undergoing constructive and some destructive interference. In consequence, the amplitude of the detector signal is spuriously changed compared with the situation where no tilt is present. Servo controls in the form of tilt compensators have been developed but they account for a major portion of the complexity and cost of the entire instrument and can easily get out of adjustment. This is not surprising when it is realized that in a translating-mirror Michelson interferometer the tilt tolerance is typically one or two arc-seconds!

The problem is particularly severe in FT spectrophotometers where a scanning assembly reciprocating along a path of the order of centimeters must be provided. In many experimental and commercial instruments, a rectilinear reciprocating motion is chosen and a great deal of ingenuity has gone into devising means for guiding the assembly so as to confine its motion to a strictly rectilinear path. Linear air bearings and servo controls have been adopted in sophisticated and, therefore, expensive systems.

A practical proposal for a simple rotary scanning assembly which circumvents the major difficulties encountered with rectilinear scanning assemblies and is inherently tilt-compensated to some extent was described by R. S. Sternberg and J. F. James, of the Physical Laboratories of Manchester University, England, in the Journal of Scientific Instruments, Vol. 41, pages 225-226, April 1964, under the title "A new type of Michelson interference spectrometer". In the introduction to their article, the authors stress the drawbacks of scanning arrangements known at the time before discussing their solution. Unfortunately, although their proposal represents an interesting and valuable approach to the problem of lessening mechanical accuracy requirements, it has not been adopted by manufacturers of FT spectrophotometers, probably because it suffers from a serious drawback, now totally eliminated by the present invention.

In modern FT spectrophotometers, the analogue signal generated by the detector is digitized and processed by a microprocessor. It is an important requirement to ensure that the path of the beam reaching the detector does not change with the angular position of the scanning assembly or the optical throughput to the detector will change in a manner which is in no way related to the analysis of the spectrophotometric sample and does in fact vitiate analytical results. It will later be shown with the aid of a drawing, before the disclosure of practical embodiments of the present invention, that such requirement is not met by the prior art proposal, in which the optical output from the scanning assembly suffers a translatory displacement, with the result that, starting from a position of the scanning assembly correspondingly to which the entry pupil of optical converging means before the detector is totally filled, more and more of the rays will miss the pupil altogether as scanning progresses from that position in either rotational direction. The drawback is of course tolerable where the analogue changes in the signal need not be measured accurately, such as when the detector output is merely used for the purpose of counting interference fringes, but is certainly unacceptable in an FT spectrophotometer wherein the spectrum of the sample must be drawn with band amplitude fidelity of a high order.

SUMMARY OF THE INVENTION

The object of the present invention is to provide interferometric apparatus including a rotary scanning assembly for varying the optical path difference between two optical paths and producing an output beam, including contributions from the two paths, which is maintained on a substantially constant path for any angle of the scanning assembly within a design range and in addition to provide an improved Michelson-type interferometer, in particular an FT spectrophotometer, incorporating said scanning assembly.

In broad terms, the above object is achieved by providing the rotary scanning assembly with an output mirror the orientation of which in conjunction with the selection of the rotational axis of the assembly enables the function referred to above to be fulfilled.

In accordance with one aspect of the present invention there is provided an interferometric apparatus comprising a rotary O.P.D. scanning assembly mounting a mirror pair formed by a beam splitter and a folding mirror, said beam splitter having a semi-reflective beam-splitting layer one face of which is the optical input surface in accurately parallel face-to-face relationship with said folding mirror and the other the output surface. Two stationary reversing mirrors co-operate with said mirror pair for (a) defining two interferometric arms, each arm receiving one of the two beams resulting from the splitting of an input beam by the beam splitter, (b) rotationally scanning successive O.P.D. values between the two beams up to a predetermined maximum, and (c) recombining the beams at said output surface so that they emerge therefrom as a single beam directed along an output path. An output mirror is provided which is mounted at right angles to the output surface of said beamsplitting layer, said output mirror being borne by the scanning assembly and positioned to receive the output beam. Suitably arranged pivotal means ensure that the scanning assembly rotates around an axis substantially coincident with the line of intersection of the prolongation planes of the semi-reflective beam-splitting layer and the face of the output mirror, respectively.

In the interferometric apparatus as defined, the specified geometric relation between the semi-reflective layer and the output mirror in conjunction with the positioning of the rotational axis of the scanning assembly enable the output beam to be directed along an output path that is substantially immutable in space for any scan angle within the design range of the assembly.

Because the output beam may be utilized in conjunction with a photosensitive device of very small active area, it may be essential for it to have particularly high spatial constancy. The T.G.S. (triglycine sulphate) detector of infra-red radiation, which is now often chosen by designers because of its high sensitivity and comparatively fast response, is such a device. With an active circular surface area only one or two millimeters in diameter, it clearly cannot tolerate any significant lateral displacement of the beam impinging thereon, even accounting for the fact that in certain applications the problem is lessened by the active area receiving in fact a demagnified stop image, e.g. demagnified Jacquinot stop image in the case of FT-IR spectrophotometers. (IR stands for Infrared).

The outstanding advantage of the part played by said specified geometric relation within the overall co-operation of the optical elements defined is that it has made the adoption of the rotary O.P.D. scanner a real feasibility in all those applications where the spatial inconstancy of the output beam associated with the prior art rotary scanner had hitherto prevented it—first and foremost in FT-spectrophotometry.

A consequence of the specified geometric relation referred to is that the beam splitter is not rotated around an axis of symmetry. This means that the cross-section of the input beam must translate across the face of the beam splitter as the scanning assembly is rotated. But even if the rotational axis were an axis of symmetry co-planar with the semi-reflective layer, the projected area of the input beam cross-section onto the beam splitter would still vary with the angle of rotation of the scanning assembly.

In accordance with another aspect of the present invention, the combined translation and projection effects may be taken into account by adopting a circular configuration for the effective area of the beam splitter and an elliptical one for the cross-section of the input beam, the major and minor axes of the ellipse being so chosen that the effective area of the beam splitter almost totally swept by the ellipse is substantially a minimum that will meet the desired optical throughput and the angular travel limits of the scanning assembly required to achieve the predetermined O.P.D. maximum value. This is tantamount to saying that the whole of the beam splitter area is utilized almost to the full.

Apart from the economical advantage enabled by the refinement, in so far as beam splitters are expensive optical elements, there is also a mechanical benefit in that the smaller beam splitter is more mechanically stable.

Although it is proposed that the rotational axis of the scanning assembly be substantially coincident with the line of intersection referred to earlier, in fact a slight departure from coincidence can be tolerated. Naturally, if coincidence is aimed at in the first place, a more symmetrical region of tolerance around the ideal axis is achieved. Because of that tolerance, the mounting of the scanning assembly is simplified. In fact, the scanning assembly may comprise an integral rotatable casting mounting the folding mirror, the beam splitter and the output mirror. It may be housed within a stationary integral casting mounting the reversing mirror, two simple pivotal connections between the two castings allowing the first to rotate relative to the second, without any need for sophisticated and, therefore, costly bearings.

An interferometric apparatus in accordance with the present invention offers particular advantages when the apparatus is in fact an FT-spectrophotometer based on a Michelson-type interferometer, especially where a reference interferometer with a laser source is incorporated. In so far as the laser beam must be made to follow the same path through the scanning assembly as the spectrophotometric input beam, the reference interferometer will itself benefit from a spatially constant output beam which is of very small cross-section and must be critically aimed at co-operating photosensitive devices of small active areas, to obtain electrical signals therefrom through which the acquisition of data points from the interferogram of the sample under analysis may be accurately timed.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 depicts a Prior Art interference spectrometer of the Michelson type incorporating a rotary O.P.D. scanning assembly;

FIG. 2 represents the interference spectrometer of FIG. 1 modified to incorporate a rotary O.P.D. scanning assembly in accordance with the present invention;

FIG. 3 is a diagram intended to illustrate that the path of the output rays of the rotary O.P.D. scanning assembly in accordance with the present invention remains substantially fixed in space for any angle of rotation of the assembly within its design range;

FIG. 4 is a symbolic layout of an FT-IR spectrophotometer incorporating a rotary O.P.D. scanning assembly in accordance with the present invention;

FIG. 5 is a practical layout corresponding to the symbolic layout of FIG. 4.

FIG. 6 refers to the FT-IR spectrophotometer of FIGS. 4 and 5 and illustrates how from a pair of electrical sine waves, each representing the interferogram of the reference laser beam incorporated in said spectrophotometer, waves are derived for timing the acquisition of data points from the interferogram of a spectrophotometric sample under analysis;

FIG. 7 is a block diagram of a microprocessor-based system for managing the FT-IR spectrophotometer described with reference to FIGS. 4 to 6; and

FIGS. 8A to 8D depict alternative beam splitter constructions suitable for use in the present invention.

DETAILED DESCRIPTION OF THE INVENTION

It is thought that the concept of the present invention, as well as one particular manner in which it may be put into effect, can best be appreciated by first describing, with the aid of FIG. 1, the prior art rotary scanning assembly referred to earlier, as part of a Michelson-type interferometer. An added advantage of this approach is the opportunity it offers to relate the foregoing generalities on the said type of interferometer to a basic diagrammatic representation.

In FIG. 1, light emitted by a source **1** stopped down by an aperture plate **2** is collimated by a positive lens **3** into an input bundle of nominally parallel rays directed towards a beam splitter **4** oriented at 45 degrees to the incoming rays and comprising a semireflective (i.e. partially reflecting and partially transmitting) layer **4A** sandwiched between transparent supporting slabs **4B** and **4C** having identical optical characteristics. Upon striking the layer **4A**, the input bundle is split into a reflected bundle portion, with a 90-degree bend, and a transmitted bundle portion.

The reflected bundle portion encounters a plane folding mirror **5** and a plane reversing mirror **6** in its travel along a forward path extending from the layer **4A** to the mirror **6**, before reversing into a return path that extends from the mirror **6** to the layer **4A** and is spatially coincident with the forward path. At the end of its return path, it partially traverses the layer **4A**, is deflected by a plain folding mirror **7** into the entry pupil of a positive lens **8**, and is finally brought to a focus at a photodetector **9**. The sum of the forward and reverse optical paths extending between the layer **4A** and the reversing mirror **6** represents a first interferometric arm of the interferometer outlined in FIG. **1**. We shall refer to this arm as the upper arm.

The transmitted bundle portion passes through the layer **4A** at the start of its travel along a forward path, strikes the plane reversing mirror **10** at the end of that path, bounces back along a return path that terminates at the layer **4A** and is spatially coincident with the forward path, is reflected by the layer **4A**, and, again, by the plane mirror **7**, into the entry pupil of the positive lens **8**, and is finally brought to a focus at the photodetector **9**. The sum of the forward and return optical paths extending between the layer **4A** and the reversing mirror **10** represents a second interferometric arm. We shall refer to this arm as the lower arm.

Since the optical path extending between the layer **4A** and the photodetector **9** is shared by the two bundle portions reaching the photodetector **9** from the two arms of the interferometer, respectively, and neither bundle portion can therefore suffer retardation with respect to the other, as long as the optical path lengths of the two interferometric arms are absolutely identical, a wavefront reaching the layer **4A** along the return path of the first interferometric arm is coincident in space with a wavefront reaching the layer **4A** along the return path of the second interferometric arm, with the result that the two wavefronts are recombined at the layer **4A** (constructive interference). If the beam splitter **4** were perfect, and no transmission losses were suffered by the rays, the recombined bundle of rays would have exactly the same intensity as the input bundle issuing from the lens **3**. Under such ideal conditions, if one were to replace the detector **9** with a diffusing screen and the source **1** emitted visible light (say, monochromatic light, to take the simplest case), one would observe a patch of light on the screen that could not be distinguished in intensity from the patch that would be seen if the screen were placed at the aperture of aperture plate **2**.

On the other hand, if the optical path length of one interferometric arm was greater than that of the other arm, the optical path difference thus established would cause the wavefronts of the light from the arm having the greater optical path length to be retarded relatively to the wavefronts from the other arm. With the wavefronts out of phase, the light patch observed on the screen at the detector location would be less intense than before by an amount related to the out of phase angle, and, in the extreme case (phase opposition), would not be visible at all (destructive interference).

In the prior art arrangement being reviewed with reference to FIG. **1**, the optical length of the lower interferometric arm is fixed and that of the upper arm is variable, which is tantamount to saying that the O.P.D. between the two arms may be varied (or modulated). To this end the beam splitter **4** and the mirrors **5** and **7** are rigidly mounted in a frame **11** rotatable around a pivot **12**, normal to the plane of the paper, and affixed to a stationary base plate (not shown) to which the remainder of the components shown in FIG. **1** are firmly attached. The frame **11** and the parts represented within it constitute an O.P.D. scanning assembly, which will henceforth be referred to more briefly as scanner **13**. As shown in FIG. **1**, the scanner **13** is in the attitude that gives exactly zero optical path difference between the two interferometric arms.

The prior art interferometer of FIG. **1** is said to be aligned (i.e. the wavefronts from the two arms recombine exactly at the beam splitter layer **4A** when the O.P.D. is zero) if:

(a) the mirror **5** is mounted accurately parallel to the beam splitter **4**;

(b) the lower-arm reversing mirror **10** is set up to image the aperture in aperture plate **2** onto itself;

(c) the upper-arm reversing mirror **6** is set up so that its image via mirror **5** and beam splitter **4** is parallel to the mirror **10**; and

(d) the mirror **7** is parallel to the beam splitter **4** to within one degree or so.

It is to be assumed that the interferometer shown has been properly aligned in accordance with the above procedure.

To change the O.P.D. between the two interferometric arms, it is merely a question of rotating the scanner **13**, say, anti-clockwise around the pivot **12**. When that is done, the optical path length of the lower arm remains unchanged but that of the upper arm increases. No motion of the scanner **13** other than the rotation—in either sense of direction—around pivot **12** can affect the O.P.D. This is essentially due to the well known properties of a pivotally mounted pair of accurately parallel plane reflectors, such as in fact represented by the layer **4A** and the mirror **5**. Such pair will ensure that, although the optical path of the upper arm is increased by the anti-clockwise rotation of the scanner **13**, the bundle of rays reaching the mirror **6** are not tilted in the process but simply translate a little lower down the mirror **6**. This result is achieved whether the pivot **12** is located as shown or anywhere else. What happens to the optical path length of the common path extending between layer **4A** and lens **8** is not important, of course, since there cannot be any O.P.D. between two common optical paths.

Unfortunately, a serious disadvantage of the scanner **13** is that not only the horizontal bundle of rays in the upper arm translate over the face of the mirror **6** but also the parallel rays directed to the lens **8** translate over the face of mirror **7**. Thus, as the scanner **13** is turned anti-clockwise, at the same time that the bundle of rays directed to mirror **6** sweeps downwards, the recombined bundle from mirror **7** sweeps upwards, with the result that its effective cross-section is increasingly reduced since it no longer fills the aperture of the lens **8**, as in FIG. **1**, but increasingly underfills it from the bottom up. It follows that the solid angle of light energy reaching the detector **9** is correspondingly decreased or, more generically, the path of the impinging rays is changing with the position of the scanner **13**.

That the rays emerging from the scanner **13** move parallel to themselves as the said scanner is rotated can be readily appreciated by observing that while the direction of the collimated bundle of rays emerging from the lens **3** is immutable that of the corresponding rays reflected by the layer **4A** changes with the angle of rotation of the scanner **13**. For anti-clockwise rotation from the attitude depicted in FIG. **1**, the reflected rays impinge on the mirror **5** at a smaller angle of incidence (i.e. the angle between an incident ray and the normal to mirror **5**) than before and, therefore, lower down the mirror face. It follows that any ray reflected by mirror **5** will also meet mirror **6** lower down the face. Since any one ray reaching the mirror **7** is the optical prolongation of a ray that impinged on mirror **5** and was returned to mirror **5** via reversing mirror **6**, it follows that said ray, say, the central ray in FIG. **1**, will impinge on mirror **7** higher up than shown,. i.e. will translate upwards.

Where the instantaneous intensity of the light reaching the detector within an area imaging the aperture stop of the interferometric system must be measured, as is the case in commercial FT optical spectrometers, the path of the rays impinging on the detector must remain constant as the O.P.D. is scanned. The prior art O.P.D. scanner shown in FIG. **1** would not, therefore, be suitable for such application.

The arrangement of FIG. **1** has been modified to produce an embodiment in accordance with the present invention whereby the output beam reaches the detector along an optical path that remains fixed in space throughout the scanned O.P.D. range, thus opening up a vast field of application for a rotary O.P.D. scanner, the considerable virtues of which—first and foremost the comparative ease with which mechanical precision of scanning can be achieved—could not be exploited hitherto owing to the scanning action giving rise to a translation of the beam emerging from the scanner.

In FIG. **2**, depicting the modified arrangement, the mirror **7** has been turned around so that it lies with its reflecting face normal to the layer **4A**. It follows that lens **8** and detector **9** are transferred to respective positions symmetrical with those occupied in FIG. **1**.

The pivoting point for the O.P.D. scanner is no longer at **12** but has been shifted to **14**, the actual axis of rotation being at the line of intersection between the prolongation of layer **4A** and that of the reflecting surface of mirror **7**, the prolongations being indicated by the intersecting dotted lines shown.

The result of the changes thus introduced is quite dramatic. As observed earlier, the location of the axis of rotation in no way affects the operation of the mirror pair represented by layer **4A** and mirror **5** in ensuring that for any angle of rotation of the scanner **13** the bundle of rays directed towards and returning from mirror **6** remain strictly perpendicular to the reflecting face of mirror **6**. It follows that in explaining the operation of the present embodiment it will be sufficient to consider the effect of re-orientating the mirror **7** and selecting the rotary axis **14** on rays emerging from the scanner **13** after passing through layer **4A** from the upper interferometer arm, combining with rays from the lower arm and bouncing off the mirror **7**. It will naturally be assumed that the modified interferometer has been aligned in accordance with the procedure described earlier for the FIG. 1 interferometer. In FIG. 3, with some reference to FIG. 2, the effect is illustrated in diagrammatic form by following the path of a single input ray **15**, from the point of emergence from lens **3** (FIG. 2) up to the scanner output, for two arbitrarily chosen angular positions of the scanner **13**: an initial position for which the angle of incidence of ray **15** on layer **4A** is 45 degrees, and a final position for which the angle of incidence is reduced to 28 degrees. The Roman numeral I added in brackets to the references **4A** and **7** denote the initial position; and the Roman numeral II similarly added to the said references, the final position. The rays associated with the initial and final positions, respectively, are similarly distinguished. In the interest of simplicity, the split rays associated with the two interferometric arms have been truncated so that only the portions that co-operate with the beam splitting layer in each of the two positions of the scanner are shown in FIG. 3.

With the scanner **13** in the initial position as indicated, the input ray **15** meets the layer **4A(I)** and after being split in rays **15A(I)** and **15B**, in the manner generally described earlier with reference to FIG. 1, is recombined as **15A(I)+15B**, ray **15A(I)** being returned by reversing mirror **6** via mirror **5** from the upper interferometric arm and ray **15B** by the reversing mirror **10** from the lower arm.

Clearly ray **15** and its recombination **15A(I)+15B** must be normal to each other since the latter is on the prolongation of **15A(I)** which is normal to **15** because it originates from a 90-degree partial reflection of ray **15** by layer **4A**. Mirror **7(I)** is normal to layer **4A(I)** and it follows that ray **15A(I)+15B** must meet it at 45 degrees with the result that ray **15A(I)+15B** is reflected at 90 degrees and exits parallel to the input ray **15**.

It will now be shown that in the final position of the scanner **13** the ray that is to be referenced **15A(II)+15B** will not only exit parallel with the ray **15** (which is also achieved by the prior art interferometer shown in FIG. 1) but it will actually lie on a path coincident with the path on which ray **15A(I)+15B** exits when the scanner **13** is in the initial position (which is not achieved by the FIG. 1 interferometer). In other words, it will be shown that in moving the scanner **13** from one to other position the exit ray stays on the same path.

With the scanner **13** in the final position, the input ray **15** meets the layer **4A(II)** at an angle of 28 degrees, as stated earlier, and a split portion **15A(II)** is deflected at twice that angle into the upper interferometric arm. The returning **15A(II)** ray recombines with the **15B** ray to form the **15A(II)+15B** ray which intersects the mirror **7(II)** at a point where the path of the ouput ray for the scanner **13** in the initial position also intercepts the mirror **7(II)**. If the normal to the mirror **7(II)** at the point of intersection bisects the angle by which the recombined ray has been deflected, then the output ray for both initial and final positions of the scanner **13** must lie on a common path. That is in fact the case, as can be easily verified for any angle of rotation of the scanner **13** within its design range. This means that the present embodiment ensures that the exit path of the ray **15** (and of course any other ray one wishes to consider) remains fixed in space, thus completely eliminating in a very simple manner the very serious drawback of the prior art proposal.

An FT-IR spectrophotometer embodying an O.P.D. scanner in accordance with the present invention and suitable for operation in the region of the infrared spectrum extending between 4000 cm^{-1} and 400 cm^{-1}, equivalent to wavelengths of 2.5 and 25 microns, respectively, is diagrammatically represented in FIG. 4.

In FIG. 4, a coiled platinum-wire IR source **1**, longitudinally extending along an axis normal to the plane of the paper, is surrounded by a cylindrical shield **1A** having a window **1B** facing the median hottest zone of the source. The shield **1A** is represented to suggest that a cross-section has been taken on a plane intersecting the said axis and bisecting the window **1B**. The whole is surrounded by a further shield **1C** with a circular window **1D** much larger than widow **1B** and similarly represented. The patch of the infrared radiation emitted by the source **1** through window **1B** that is actually utilized in the spectrophotometer is not determined by either window **1B** or window **1D** but by the post-source optics, as will be presently shown. A principal ray and two pairs of marginal rays, one pair from each lateral end of the utilizated patch are traced through the entire system.

The infrared rays as defined impinge upon an elliptical mirror **16**, one focal region of which coincides with the radiation patch at the source **1**, and the other with circular aperture **2A** in plate **2**, of such diameter that the said aperture is overfilled all round by the image of said patch. A baffle plate **17** located at a pupil position positively defines the effective aperture of the mirror **16** by virtue of an aperture **17A** shaped in the form of an ellipse having major and minor axes predetermined for a purpose to be presently described, and a plane mirror **18** folds the rays emerging from the aperture **17A** onto the aperture **2A**. The arrangement so far described serves to image the radiation patch from the source **1** at the aperture **2A**, with the result that the radiation-filled circular aperture **2A** becomes the effective source with a well defined imagery and being overfilled effectively determines the area of the radiation patch actually utilized. In sum, it represents the aperture stop (or Jacquinot stop) of the system.

A second plane mirror **19** folds the beam emerging from aperture **2A** onto parabolic mirror **20**, the length of the optical path between the latter two elements being approximately equal to the focal distance of the mirror **20**, which acts therefore as a collimator and may be regarded as the optical counterpart of the lens **3** in FIGS. 1 and 2. Since the source **1** is not a spot source but is intended to be a finite area source, collimation is approximate but adequate nevertheless.

In addition, mirror **20** images the elliptical aperture **17A** onto the reversing mirrors **6** and **10**. The major and minor axes of the elliptical patch of radiation projected have been chosen to ensure efficient utilization of the circular active area of the beam splitter for a given optical throughput and O.P.D. scan range, bearing in mind that in the present embodiment the collimated beam actually translates over the beam splitter surface, as reference to FIG. 3 will show. Further elaboration of this feature, which is believed to be novel per se, will be given after the description of FIG. 5.

The collimated beam produced by the parabolic mirror **20** forms the optical input to the interferometric optics proper, wherein the semi-reflecting layer **4A** of beam splitter **4** forming part of the O.P.D. scanner **13**, within the boundary of frame **11** shown in dashed lines, co-operates through its upper folding mirror **5** with the fixed reversing mirror **6** to define the upper interferometric arm and, through the lower folding mirror **21**, with the reversing mirror **10** to define the lower interferometric arm. Note that the mirror **21** enables optical symmetry to be established between the two interferometric arms.

The beam recombined at the beam splitter **4** in the manner described earlier exits from the scanner **13** via the outut mirror **7**, which performs the all-important function already explained with reference to FIGS. **2** and **3**. A parabolic mirror **22** converges the output beam from the scanner **13** onto its focal region, whereat an image of the Jacquinot stop is projected and a thinly layered analytical sample borne upon a carrier **23** is to be located. An elliptical mirror **24** is so designed and positioned that said image spatially coincides with its first focal region and is relayed with a de-magnification of approximately 6:1 to its second focal region, which is occupied by the sensitive surface of detector **9**.

Note that the analytical sample and its carrier may assume any of the convenient forms well-known in the art. A thinly-layered sample has been indicated because it is a commonly used form and may be readily related to the nominal plane of the Jacquinot stop image.

All the components shown in FIG. **4**, with the exception of those within frame **11** forming part of scanner **13**, are rigidly mounted on a base plate, not shown in FIG. **4** but represented in the constructional drawing of FIG. **5**. Scanner **13** is rotatable to and fro between two limit positions around axis **14** within a housing itself fixed to the base plate, as will be described with reference to FIG. **5**.

As shown in FIG. **4**, the scanner **13** is midway between its limit positions and provides zero O.P.D. between the two interferometric arms. The two limits, attained by clockwise and anti-clockwise rotation, respectively, correspond to O.P.D. values that are equal but of opposite sign. In fact, clockwise rotation of the scanner from the position shown increases the optical path length of the variable interferometric arm and anti-clockwise rotation decreases it. It is therefore convenient to refer to the clockwise O.P.D. limit as L_{max+} and the anti-clockwise as L_{max-}. By swinging the scanner **13** from one to other limit, a complete double-sided interferogram is generated, as required for the purpose of computing its Fourier Transform. In the present embodiment, L_{max} is 2 cm and the scan time between L_{max} and zero O.P.D. is 1 second.

For a purpose that presently will be referred to in some detail, a reference monochromatic interferometer is inserted in the optics of the main interferometer, forming part of the FT-IR spectrophotometer described, so that they share the scanner **13**. The reference interferometer comprises, in addition to the shared scanner **13**, a low-power laser **25** providing a line of monochromatic plane-polarized radiation at a wavelength of 632.814 nanometers. The plane-polarized beam issuing from the laser **25** is passed through the scanner **13** via a small plane mirror **26** located in the collimated beam produced by parabolic mirror **20** and is recovered from the collimated beam at the output of scanner **13** for directing to sensor unit **27** via plane mirror **28** co-operating with mirror **29**. In passing through the scanner **13**, the beam traverses a ⅛-wave plate **30** and is affectd thereby in a manner that will be presently indicated. At the sensor unit **27**, a beam splitter **27A** permits a transmitted part of the laser beam to reach a photosensor **27B** without a change in direction and a reflected part to reach a photosensor **27C** with a 90-degree deflection, the axis of the two sensors being spaced 90 degrees apart. For a purpose to be considered later, plane polarizers **27B1** and **27C1** are positioned before photosensors **27B** and **27C**, respectively, with their transmission planes crossed.

In FIG. **5** the diagrammatic representation of FIG. **4** has been translated into an engineering layout of real components, with only the chief ray CF shown to trace the optical path from the source **1** to the detector **9**. It is believed that FIGS. **4** and **5** together facilitate a proper appreciation of function and construction in the realization of an O.P.D. scanner per se and as part of an FT-IR spectrophotometer, both in accordance with the present invention. Incidentally, although the mechanical precision requirements are made less stringent by confining operation to the infrared region of the electromagnetic spectrum, the rotary O.P.D. scanner in accordance with the present invention enables high precision to be advantageously attained in regions of the spectrum of shorter wavelengths.

In the description that follows, references identifying elements shown diagrammatically in FIG. **4** will also identify the corresponding real components in FIG. **5**. Of these, the mirrors **16, 18, 19, 20, 22** and **24** need no further elaboration except for pointing out that they are supported on brackets **16A, 18A, 19A, 20A, 22A** and **24A**, respectively, for fixing by means of screws **16B, 18B, 19B, 20B, 22B** and **24B** to a rigid base plate **31**, as shown. It will be noted, in addition, that the detector **9** is mounted on an L-shaped bracket **9A** which is itself attached to an extension of bracket **24A** mounting mirror **24**, and that the sample carrier plate **23** is slid, in use, into channels **23A** formed in a guide plate **23B** fixed to a bracket **23C** for mounting on the base plate **31** by means of screws **23D**, the sample having been made fast to the carrier **23** over the circular aperture **23E** by any suitable means well known in the spectroscopic art. Furthermore, the baffle **17** and the Jacquinot stop **2** form a combined unit P made of sheet metal in which the aperture of the former is oval and that of the latter circular. A bottom flange P1 enables the unit P to be screwed to the base plate **31** by screws P1A.

The source **1**, complete with its outer shield **1C**, is mounted vertically between the limbs of a U-shaped bracket **1E** that is itself attached to the upright limb of an L-shaped bracket **1F** in turn affixed, through the other limb of the L, to the base plate **31** by screws such as **1G**.

Attention is now particularly directed to the bottom left-hand corner of FIG. **5**, whereat two castings are shown, one comprising three integral sections **11A, 11B, 11C** forming one part of the O.P.D. scanner **13** and the other, referenced **32**, providing essentially a housing within which the scanner **13** is rotatably mounted in a manner to be described.

Casting **11A-11B-11C**, which may be regarded as an engineered version of the frame **11** diagrammatically shown in FIG. **2**, comprises a box-like centre section **11A** extending, to the right, into a flag **11B** and, to the left, into a drive arm **11C**. The centre section **11A** has a wall **11A1** provided with an aperture **11A2** into which a beam splitter **4** of circular configuration is fixedly mounted and a facing wall **11A3** mounting folding mirror **5**, which is also circular.

As shown in FIG. **5**, the beam splitter **4** is of the same construction as the beam splitter **4** in FIG. **4**, in that it comprises a semi-reflective layer sandwiched between two supporting slabs transparent to the radiation emanating from the source **1** and having identical optical characteristics. However, the semi-reflective layer **4A** (FIG. **4**) may alternatively be provided on a taut film transparent to said radiation. It may also take the form of a specular foraminous structure such as a mesh or a grid, in which case the layer represented by the structure is semi-reflective by virtue of the lack of reflection from the open spaces in said structure. The structure may be self-supporting or carried on a transparent taut film. In the latter case, it could be provided as a layer vacuum evaporated onto the film.

Alternative beam splitter constructions as referred to are depicted in FIGS. **8A** to **8D**. In each figure, a ring frame **4D** forms a carrier for a semi-reflective layer. In FIG. **8A**, the frame **4D** supportes closely spaced, stretched, parallel wires forming a grid **4E**; in FIG. **8B**, the two sets of parallel wires intersect to define a mesh **4F**. FIGS. **8C** and **8D**, which are cross-sections of perspective views along a diameter of the frame **4D**, depict a grid **4G** and a mesh **4H**, respectively, as vacuum deposited layers on a transparent film **4K** stretched over the frame **4D**.

The flag **11B** acts as a carrier for rectangular mirror **7**, which is rigidly supported normal to the beam splitter **4**. The region where the flag **11B** extends from the centre section **11A** includes the line of intersection between the surface prolongations of mirror **7** and reflecting layer **4A** of beam splitter **4**. An upper boss **11A4** is formed in an upper wall **11A5** of section **11A**, roughly concentric with the said line of intersection. Within the boss **11A4** a V-shaped bearing **11A4A** is provided. Similarly, a lower boss **11A6** is provided in a lower wall **11A7** of section **11A** which is roughly concentric with the line of intersection. Within the boss **11A6** a ball bearing **11A8** is fixedly mounted.

The drive arm **11C** has an end boss **11C1** acting as a bearing to a pin **11C2** connecting one end of a plate **11C3** to one end of a plate **11C4**, the two plates forming a linkage **11C5** which further comprises another pin **11C6** joining the remaining two ends of the plates and rotatable in a block **11C7**. The housing **32** comprises a floor **32A**, having holed bosses such as **32B** through which screws such as **32C** are passed for fixing the housing **32** to the base plate **31** through resilient mountings such as **32C1**, and a roof **32D** spacedly supported by intervening vertical members such as integral pillar **32E**. A cylindrical pivot **32F** that is a forced fit in boss **32G** is provided for engaging the V-shaped bearing **11A4A** in boss **11A4**. A recess (not shown) in the floor **32A** houses a spherical bearing member (not shown) for engaging the ball bearing **11A8** in boss **11A6**. The axis of rotational symmetry of the pivot **32F** and that of said spherical bearing member coincide with the line of intersection referred to earlier and the ball bearing **11A8** is mounted so that a diameter thereof also coincides with said line. It follows that the arrangement described pivotally mounts the scanner **13** in the housing **32** for rotation around an axis which coincides with said line of intersection, i.e. axis **14**. Moreover, the location of the axis creates a weight offset towards the front in the scanner **13** as seen in FIG. **5**, with the result that the V-shaped bearing **11A4A** is urged by gravity into contact with the pivot **32F**.

One of the vertical spacing members between the roof **32D** and the floor **32A** is mirror carrying structure **32G** provided with vertical walls **32G1** and **32G2**, supporting mirrors **6** and **10**, respectively, the said walls being oriented so as to locate the mirrors in the correct angular positions diagrammatically illustrated in FIG. **4**. A further member **32H** in the form of a pillar of rectangular cross-section is used to mount the mirror **21**.

The drive means for rotating the scanner **13** to and fro within two predetermined angular limits relative to the housing **32** will now be described. One end of a drive shaft **33** solidal with a cylindrical drive roller **34** is free to rotate in block **11C7** but is longitudinally captive thereto. The shaft **33** is further pivotally supported at its other end in a plain sleeve bearing **35** mounted in one limb **36A** of a U-shaped bracket **36** fixed to the floor **32A** by screws such as **36B**, said sleeve bearing **35** additionally allowing freedom of axial displacement. The drive shaft **33** includes an integrally formed lead screw portion **33A** engaging a mating thread in the other arm **36C** of bracket **36**. The drive shaft **33** may be rotated in either direction by an electric motor **37** via a belt **38** forming a drive linkage between a pulley **39** mounted on motor shaft **40** and the cylinder **34**. The motor **37** is mounted on a bracket **41** affixed to the U-bracket **36** by screws such as **42**. Assuming that the lead screw **33A** is righthanded, clock-wise rotation of the motor shaft **40** causes the drive shaft **33** to move forward, thus urging the scanner **13** to turn in a clock-wise direction, the gradually changing angle between the drive shaft **33** and the drive arm **11C** in a plane parallel to the floor **32A** and passing through the axis of shaft **33** being taken up without restraint by the action of the linkage **11C5**. At the same time the belt **38** will not impose more than a negligible restraint on the longitudinal motion of the shaft **33** by virtue of the fact that the side thrust in its engagement with the cylinder **34** introduced by said motion will cause it to slip axially of the cylinder **34**. The operation for anti-clockwise rotation of the shaft **33** is, of course, similar although the direction of the side thrust is reversed.

An overhanging portion **32L** of the roof **32D** supports the laser **25** through saddles, of which only saddle **25A** is visible, co-operating with straps **25B**. The mirror **26** is mounted on a stem **26A** terminating in a circular foot **26B** attached to the floor **32A** by screws (not shown). The $\frac{1}{8}$-wave plate **30** is contained within a cylindrical housing **30A** supported by a stem **30B** terminating in a rectangular foot **30C** screwed by screws **30D** to the floor **32A**. Mirror **28** is mounted in the same manner as mirror **26**, stem **28A**, foot **28B** and fixing screws **28C** being clearly visible. Mirror **29** is provided with a rear stem fitting in a hole drilled in the pillar **32H**, the stem and the hole being hidden.

A cylindrical body **27F** in unit **27** is provided with recesses in which suitably oriented machined faces **27A1**, **27B1**, **27C1**, **27D1** and **27E1** adhesively support the already introduced elements **27A**, **27B**, **27C**, **27D** and **27E**, respectively.

The electrical elements shown in FIG. **5** are inserted in an electrical operating system co-operating with the mechanical parts hereinbefore described. The laser **25** is energized through a modular power supply **25C**, the latter being connected to a public-supply outlet via a power and instrument control pack **43** having a lead **43A** terminating in a plug **43B** for connection to said outlet. Leads from the detector **9**, photosensors **27B** and **27C** and drive motor **37** also extend into pack **43**, which includes, in addition to power supply circuitry, the whole of the hardware represented in the block diagram of FIG. **7**, with the exception, of course, of a Video Display Unit and Keyboard that will be presently introduced and the blocks representing the detector **9**, the motor **37** and the unit **27**, of course.

A procedure is now described for defining the major and minor axes of the elliptical patch of radiation introduced earlier in this disclosure. In such procedure, the area of the patch is an immutable datum, fixed by the desired radiation throughput of the instrument.

A satisfactory approach is to estimate, in the first instance, a likely value for the minor axis of the ellipse formed on the beam splitter **4** (FIGS. **4** and **5**) when the scanner **13** is in the angular position corresponding to zero O.P.D. and to carry out a trace of the principal rays passing through the respective extremities of the estimated minor axis as the scanner is "swung" first to one scan limit (L_{max+}) and then to the other (L_{max-}), in order to find the respective intersects with the beam splitter **4** at said limits. The trace will, of course, account for the different angles of incidence in the presence of the compounding effect of the translation of the ellipse over the face of the beam splitter **4** caused by the rotation of the scanner **13** around an axis that is offset from the major axis of the ellipse.

Now, the area of the beam splitter **4** is minimized if the intercepts referred to and the extremities of the major axis lie on the same circle. This is tantamount to saying that the distance between the intercepts must set the length of the major axis. If the simple equation:

$$\pi \cdot a \cdot b = A$$

wherein

a = major semiaxis

b = minor semiaxis

A = area of ellipse for required throughput

is met, the predicted value for the minor axis was correct. If not, the ray trace is repeated using a lower or higher value (whichever is suggested by the previous result) until an ellipse is found that meets the throughput requirement and allows the scanning range to be covered in a circular beam splitter of minimum area. A few iterations may be needed to achieve this.

Referring to FIG. **4** once again, it should be noted that the reason for imaging the elliptical aperture **17A** onto the reversing mirrors **6** and **10**, rather than the beam splitter **4** itself, is the excessive broadening of the beam returning to the beam splitter from the two reversing mirrors that would otherwise result. The ellipse the geometry of which is determined in the manner hereinbefore described is that produced by the returning beams, and although these must still diverge, by controlling the distance between each reversing mirror and the beam splitter, the broadening can be kept within limits that ensure an efficient utilization of the beam splitter area.

Once the ellipse has been defined, it is merely a matter of arranging the length of the optical paths between (a) the mirror **20** and the baffle plate **17** and (b) the mirror **20**, the beam splitter **4** and reversing mirrors **6** and **10**, respectively. In general, once the matching optical paths between the beam splitter **4** and the reversing mirrors **6** and **10**, respectively, have been settled, one need only select the optical layout that will give conveniently scaled (e.g. demagnified) images of aperture **17A** so that the patch of radiation produced on the beam splitter by the beams returning thereto from said images fits the ellipse calculated in accordance with the method described above.

Before introducing the block diagram of FIG. **7** illustrating the microprocessor-based system for managing the FT-IR spectrophotometer of FIGS. **4** and **5**, it is thought desirable to dwell on certain generalities respecting the operation of the scanner **13**, the reference interferometer based on the laser **25** and the acquisition of interferogram data points, in both downscanning and upscanning, for the purposes of digital processing. In the present context, the term downscanning (or downscan) denotes that the O.P.D. of the variable interferometric arm is being changed from L_{max+} to L_{max-} and upscanning (or upscan) that it is being changed from L_{max-} to L_{max+}.

As indicated earlier, the scanner **13** reciprocates between two maximum retardation limits corresponding to angular positions which are symmetrical with respect to the angular datum position depicted in FIGS. **4** and **5**, at which the O.P.D. is nominally zero.

The double-sided interferogram of the source **1**, as modified by the sample in carrier **23**, produced at each limit-to-limit scan is transduced into a time varying electrical signal waveform at the output of the detector **9**. This analogue signal is, of course, unsuitable for digital processing without first undergoing analogue to digital conversion, which involves sampling the waveform at accurately repeatable O.P.D. scanning increments.

In the present embodiment, sampling is synchronized with the zero crossings of an electrical reference sine wave representing the interferogram of the laser **25** and each sampling point is constantly tracked through a counter so that successive values sampled at that point through repetitive scanning are always associated with the same counter reading and can therefore be accumulated at a digital storage location associated with said reading. In view of the scanning sequence adopted, a refinement is introduced to permit the counter to count up during upscanning and down during downscanning. The refinement consists in duplicating the reference sine wave with a 90 degree phase shift. This is achieved by the simple expedient of introducing the ⅛-wave plate **30** referred to earlier, which being traversed twice by the polarized beam from laser **25** acts on it as if it were a ¼-wave plate traversed once and, therefore, produces circular polarization of the laser beam. The original plane polarized sine wave is now accompanied by a sine wave of the same frequency 90 degrees apart. The polarizers **27D** and **27E** in unit **27** are crossed in such manner that the photosensors **27B** and **27C**, respectively associated with them, can each pass only the sine wave encountering a plane of transmission at the correct angle for access. The end result is that one optical sine wave is transduced in a related electrical sine wave by photosensor **27B** and the other by photosensor **27C**.

How the two electrical sine waves are used for the purpose of the present embodiment is now explained with reference to FIG. **6**, wherein A and B represent the said sine waves, 90 degrees apart, **A1**, **B1** the waves resulting from squaring them and **A2**, **B2** those resulting from differentiating the square waves **A1**, **B1**. Now, each pulse occurring in **A2** is used to control the sampling and processing of one data point and at the same time update a counter to be identified later with reference to the block diagram of FIG. **7**.

Assuming that the phase relationship of A2 and B2 corresponds to a downscan as indicated by arrow C, then the occurrence of a positive pulse in B2 immediately following a positive pulse in A2 is sensed and used to decrement the counter. Conversely, a positive going pulse in A2 is not immediately followed by a like pulse in B2 is associated with an upscan (arrow C1) and the counter incremented.

Upon switching on the FT-IR spectrometer, the counter is zeroed at the first zero crossing in the A2 wave immediately following the peak of the centreburst in the interferogram of the analytical sample. Thereafter, and until the instrument is switched off, the counter keeps track of the sampling points in upscanning and downscanning.

The block diagram of FIG. 7 illustrating a microprocessor-based system for the control of the FT-IR spectrophotometer depicted in FIGS. 4 and 5 will now be described.

In FIG. 7, the signal from detector **9**, amplified by amplifier **43**, is fed into sample and hold unit **44** and each sampled value is routed to analogue-to-digital converter **45** feeding into microprocessor **46**. The output of unit **27**, consisting of two sine waves 90 degrees apart, as described earlier, is passed through an amplifier **47**, after which each sine wave is squared in unit **48**. Each resulting square wave is differentiated in differentiator **49**. One output of differentiator **49**, corresponding to differentiated wave A2 (FIG. **6**), is used in trigger pulse generator **50** to activate at each peak, regardless of polarity, the sample and hold unit **44** under the control of microprocessor **46** and the same output is extended to up and down counter **51**.

When the FT-IR spectrophotometer is first switched on, the counter **51** must be zeroed correspondingly to a predeterminedly fixed angular position of scanner **13** (FIGS. **4** and **5**) in order that it may thereafter keep track of all sampling points until the instrument is switched off. This achieved through a counter phase up unit **52**, which at a time when the microprocessor **46** determines that the maximum level in the amplitude of the centreburst of the sample interferogram has been reached sets the counter **51** to count from the next peak of the differentiated wave A2 in unit **49** that also supplies an input to the trigger pulse generator **50**, as stated earlier.

The scan motor **37** energized by drive circuits **53** responsive to scan motor control **54** is continuously steered in operation by the microprocessor **46** through the said scan motor control **54**, the actual count in counter **51** determining the scan action to be taken. Changes in scan direction are sensed by upscan/downscan sensor **55**, to which counter **51** responds by making the appropriate change in counting direction.

It can now be readily appreciated that each of the retardation limits must correspond to a definite and immutable counter reading. When the microprocessor **46** detects that reading, it sends a reverse signal to the scan motor control **54** and, at the same time, interrupts the processing of data points. The scan motor **37** begins its reversal procedure and the counter keeps on counting. When the count is restored to that obtaining when data processing was interrupted, the processing of data is resumed until the sampling point corresponding to the opposite retardation limit is reached, when the reversal operation is again carried out. The scan overruns by a few dummy sampling points past a retardation limit and, when the motor actually stops and reverses, the counter decrements (if before reversal upscanning was operative) or increments (if downscanning was operative) by the same number of counts as the number of sampling points overrun.

It is important to observe that by keeping track of sampling points through up and down counter **51** data points may be accumulated in upscan and downscan and correctly routed to their respective memory locations for signal averaging of data recurring at the same sampling points in successive interferograms. In addition, the scan motor reversal procedure is greatly simplified.

A video display unit **56** linked to the microprocessor **46** is included to enable the user to examine a display of sample interferograms and spectra, as well as other data. The Fourier Transform mathematical process is carried out by the microprocessor **46** which is programmed to respond to instructions keyed in by the user on the keyboard **57**.

It is to be understood that in the context of the present disclosure the term "light" includes the "invisible" regions of the light spectrum.

By incorporating a rotary O.P.D. scanner in accordance with the present invention in an FT-IR spectrophotometer as described, it has been possible to realize an instrument that is accurate, simple, comparatively inexpensive and highly reliable.

I claim:

1. Interferometric apparatus comprising:

(a) a rotary O.P.D. scanning assembly mounting a mirror pair formed by a beam splitter and a folding mirror, said beam splitter having a semi-reflective beam-splitting layer one face of which is the optical input surface in accurately parallel face-to-face relationship with said folding mirror and the other the output surface;

(b) two stationary reversing mirrors co-operating with said mirror pair for defining two interferometric arms, each arm receiving one of the two beams resulting from the splitting of an input beam by the beam splitter, for rotationally scanning successive O.P.D. values between the two beams up to a predetermined maximum, and for recombining the beams at said output surface so that they emerge therefrom as a single beam directed along an output path;

(c) an output mirror mounted at right angles to the output surface of said beam splitting layer, said output mirror being borne by the scanning assembly and positioned to receive the output beam; and

(d) pivotal means arranged to ensure that the scanning assembly rotates around an axis substantially coincident with the line of intersection of the prolongation planes of the semi-reflective beam-splitting layer and the face of the output mirror, respectively.

2. Apparatus as claimed in claim **1**, wherein the beam splitter has an effective area of generally circular configuration and said apparatus further comprises optical beam control means for projecting onto said input surface an input beam the cross-sectional area of which is an ellipse, the minor axis of the ellipse being chosen so that the distance separating the intercepts of the minor axis extremities with the input surface at two opposite predetermined angular travel limits of the scanning assembly is close to the length of the major axis and at the same time the said cross-sectional area is adequate to provide the desired optical throughput of the apparatus.

3. Apparatus as claimed in claim **2**, wherein said apparatus includes a source of light for producing said input beam and the optical beam control means comprise image forming means and a baffle which are located between the source and the beam splitter, the baffle having an elliptical aperture the major and minor axes of which together with the optical arrangement of the image forming means are such that the major and minor axes of the largest projection of said aperture on the semi-transparent layer are approximately equal to the desired major and minor axes, respectively, of the ellipse.

4. Apparatus as claimed in claim **1**, wherein the O.P.D. scanning assembly is a pivoted integral casting supporting in predetermined spaced relation the folding mirror, the beam splitter and the output mirror.

5. Apparatus as claimed in claim **4**, including a housing in the form of another integral casting wherein the O.P.D. scanning assembly is pivotally mounted, the two stationary reversing mirrors being fixed to said housing.

6. Apparatus as claimed in claim **5**, wherein in the operative attitude of the apparatus the axis of rotation of the O.P.D. scanning assembly is generally vertically oriented, said axis spanning an upper and a lower pivotal connection between the two castings, the upper connection comprising a cylindrical member fixed to one casting radially biassed into a V-shaped bearing provided in a member fixed to the other casting.

7. Apparatus as claimed in claim **6**, wherein the lower pivotal connection is of the type wherein by virtue of its own weight the pivoted casting creates a centralizing force component restraining all radial movement thereof as mechanical wear takes place.

8. Apparatus as claimed in claim **1**, including a base plate and a housing for said O.P.D. scanning assembly resiliently mounted on said base plate.

9. Apparatus as claimed in claim **8**, wherein a photosensitive device is attached to the base plate for receiving the output beam from the output mirror.

10. Apparatus as claimed in claim **1**, wherein the semi-reflective layer is held between two rigid supports transparent to the input beam and having identical optical characteristics.

11. Apparatus as claimed in claim **1**, wherein the semi-reflective layer is supported on a thin taut film transparent to the input beam.

12. Apparatus as claimed in claim **1**, wherein the semi-reflective layer is a specular foraminous structure, which is semi-reflective by virtue of the lack of reflection from the open spaces in said structure.

13. Apparatus as claimed in claim **12**, wherein said structure is self-supporting.

14. Apparatus as claimed in claim **12**, wherein said structure is supported on a transparent taut film.

15. Apparatus as claimed in claim **14**, wherein said structure is in the form of a layer vacuum evaporated on said film.

16. Apparatus as claimed in claim **1**, wherein said apparatus is an FT spectrophotometer including a Michelson-type interferometer and a detector for receiving the output beam and transducing the optical interferograms conveyed by said beam into an electrical representation.

17. Apparatus as claimed in claim **16**, comprising; a reference interferometer, incorporated within the Michelson-type interferometer, having a laser source for providing a narrow, plane-polarized, monochromatic beam; means for directing the laser beam through the O.P.D. scanning assembly along a path shared with the input beam, split beams and output beam up to and including a portion of the output path emerging from the output mirror; means for diverting the laser beam past the output mirror into a path distinct from the remainder of the output path leading to the detector; means for circularly polarizing the laser beam and thus producing two optical interferograms of the laser beam 90 degrees apart; a two-channel photoelectric transducer for transducing the said optical interferograms, one in each channel, into corresponding electrical sine waves 90 electrical degrees apart keyed to the angular travel of the scanning assembly; means for utilizing the sine waves for controlling the acquisition timing of data points from the detector output representing an analytical interferogram; and means for performing the Fourier Transform of the analytical interferogram and thus producing an electrical representation of the spectrum of a sample under analysis.

FIG. 9

HIGH FREQUENCY RECTENNA

BACKGROUND OF THE INVENTION

The United States Government has rights in this invention pursuant to Contract No. W-7405-ENG-48 between the U.S. Department of Energy and the University of California, for the operation of Lawrence Livermore National Laboratory.

A rectenna, or rectifying antenna, comprises an antenna and a diode rectifier. In operation, the antenna gathers electromagnetic energy at a frequency consistent with its size and shape, and the diode rectifies that energy into D.C. current.

Presently, rectennas utilize a semiconductor diode or large vacuum diode to rectify electromagnetic waves, with frequencies ranging up to the radio frequency spectrum, to direct current. Rectennas utilizing a semiconductor diode have an upper frequency limit and an upper intensity limit due to the inherent limitations of semiconductor diodes. These limitations include the device capacitance and the fragility of high speed semiconductor devices. Rectennas using large vacuum tubes also have upper frequency limits and are expensive to build. Large arrays of rectennas using conventional vacuum tubes would be prohibitively expensive to build, and could not be produced in a compact form.

William C. Brown in "The History of Power Transmission of the Rectenna," in the IEEE Transactions on Microwave Theory and Techniques, Vol. MTT-32, No. 9, September 1984, describes the development of rectennas for rectifying electromagnetic signals with a frequency of 2.45 Giga Hertz (GHz). The article describes research into an apparatus that would be able to allow power to be sent from the earth to a device above the earth or to allow power to be sent from above the earth to the earth via a 2.45 GHz radio signal. The author states that the best diodes that he found for the rectennas are either silicon or gallium arsenide (GaAs) Schottky-barrier diodes.

William C. Brown in "Rectenna Technology Program: Ultra Light 2.45 GHz Rectenna and 20 GHz Rectenna," published by NASA as PT-6902, CR 179558, Mar. 11, 1987 describes the development of a 2.45 GHz rectenna and proposes a 20 GHz rectenna. The article first describes the development of a 2.45 GHz rectenna. The GaAs Schottky barrier diodes for the 2.45 GHz rectenna have specifications including a zero bias capacitance of 3 pf and a reverse breakdown voltage of 60–70 volts. These specifications and other qualities of the Schottky barrier diodes limit the efficiency and the maximum power capabilities of these rectennas. The article goes on to propose a 20 GHz and higher frequency rectenna. The article states that the losses in the diode will be considerably greater at these higher frequencies and the losses in the scaled circuit structure will become greater by the square root of the frequency scaling factor because of skin losses. Because semiconductor diodes break down at high temperatures, semiconductor diodes must be cooled. In the design proposed in the article for a 20 GHz rectenna, reasonable cooling is provided if the rectenna is limited to a DC power output of 0.4 watts per diode element with an output voltage of 8.9 volts and a reverse voltage breakdown of 20 volts. At higher intensities, the resistance in the rectenna will create more heat elevating the semiconductor temperature and causing the semiconductor to breakdown. These parameters help illustrate the inefficiency and fragileness of semiconductor diodes in a rectenna.

Because of the inherent limitations of semiconductor rectennas and large vacuum tube rectennas, there is a need for rectennas that can rectify high frequency and high intensity electromagnetic waves.

The invention provides an array of rectennas, which are able to rectify high frequency microwave or high frequency and high intensity electromagnetic radiation. These arrays may be useful in transportation of power through electromagnetic waves and conversion of intense high frequency electromagnetic radiation into direct current. Applications of the invention include sending power to satellites or high altitude devices from the earth by electromagnetic waves, transmission of power from satellites which collect solar power and convert it to electromagnetic waves which are transmitted to the earth, and direct conversion of microwaves generated by fusion reactions into a direct current.

SUMMARY OF THE INVENTION

It is an object of the invention to provide a rectenna which can rectify electromagnetic radiation with wavelengths equal to or shorter than the wavelengths of microwaves.

It is another object of the invention to provide a rectenna which can rectify electromagnetic waves at high intensities.

It is another object of the invention to provide a rectenna which can rectify electromagnetic radiation with wavelengths equal to or shorter than the wavelengths of microwaves and with high intensities, and with an efficiency greater than 40%.

It is another object of the invention to provide a rectenna which is resilient to high energy radiation and high temperatures.

It is another object of the invention to provide an array of rectennas which can be manufactured in large numbers at a low cost.

It is another object of the invention to provide a compact array of rectennas.

Additional objectives, advantages and novel features of the invention will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following or may be learned by practice of the invention. The objects and advantages of the invention may be realized and attained by means of the instrumentalities and combinations particularly pointed out in the appended claims.

The invention comprises an antenna, comprising a first half and a second half, and at least one field emission vacuum diode electrically connected between the first half and the second half of the antenna to provide a rectenna. The diode is made an integral part of the antenna so that arrays of rectennas can be used for rectifying electromagnetic radiation with a frequency higher than or equal to microwave frequencies. If the diode was not integral to the antenna, and if an array of antennas was connected together, then phase differences from one side of the array to the other would cause the combined outputs to cancel, significantly decreasing the output. By making the diode an integral part of the antenna, the current is rectified at the source, and phase differences will have little effect on the combined currents.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated and form a part of the specification, illustrate several embodiments of the invention and, together with the description, serve to explain the principles of the invention.

FIG. 1 is a top view of a preferred embodiment of the invention. It illustrates a half wave rectenna using a dipole antenna and a single lateral field emission diode.

FIG. 2 is a cross-sectional view of a half wave rectenna illustrated in FIG. 1 along lines 2.

FIG. 3 is a top view of another embodiment, a half wave rectenna using a folded dipole antenna and a single lateral field emission diode.

FIG. 4 is a cross-sectional view of a half wave rectenna illustrated in FIG. 3 along lines 4.

FIG. 5 is a top view of another embodiment, a full wave rectenna using a dipole antenna and a full wave bridge rectifier using four lateral field emission diodes.

FIG. 6 is a top view of an array of half wave rectennas in parallel.

FIG. 7 is a top view of an array of full wave rectennas in series.

FIG. 8 is a top view of another embodiment, a half wave rectenna using a dipole antenna and a single vertical field emission diode rectifier.

FIG. 9 is a cross-sectional view of a half wave rectenna illustrated in FIG. 8 along lines 9.

DESCRIPTIONS OF THE PREFERRED EMBODIMENTS

FIGS. 1 and 2 show a top and side view of a preferred embodiment of the invention. The invention receives and rectifies an electromagnetic wave with wavelength L. It includes a dipole antenna (1 and 3), coupled with an integral lateral field emission diode 2 at the center, and an external capacitor 6. In the preferred embodiment the total length 10 of the dipole antenna is approximately L/2.

The embodiment may be constructed using conventional semiconductor manufacturing techniques on an insulating substrate 4 attached to a conducting ground plane 5 (FIG. 2). The ground plane makes the antenna directional, with the vertical direction being the preferred direction. The separation 155 between the antenna and the ground plane is preferably approximately L/4 to provide a maximum reflection of electromagnetic radiation which passes through the antenna 1 and 3 to the ground plane. The actual distance would depend on the material used as the insulating substrate.

Using conventional semiconductor techniques, a layer of conductive material (tungsten, or doped polysilicon for example) is deposited on the insulator and then shaped by photolithography and wet or dry etching. The insulator under the layer of conductive material is then etched, undercutting the conductor. This undercutting frees the edge of the conductor to prevent surface leakage currents and surface breakdown along the insulator between the two sides of the antenna.

The method of making a field emission vacuum triode is disclosed in U.S. Pat. No. 4,855,636 by Busta et al, which is incorporated by reference. Using the method described in Busta et al. a field emission diode in a vacuum could be created. By using a differently shaped mask the field emission diode can be integrated into a dipole antenna. Even though Busta discloses the creation of a triode, the field emission diode could be created in a similar manner by either sealing the etching holes described in Busta with an insulating material or by not applying a charge to the gate of the triode. For cases where the mean free path of an electron in a gas at some pressure is comparable to the separation of the anode and cathode, the diode will operate in that gas at that pressure as if it were in a vacuum. In addition, a low pressure or near vacuum can also be established around the field emission diode by sealing the entire rectenna in a near vacuum container.

Electromagnetic radiation of wavelength L is absorbed by the dipole antenna 1 and 3. According to well known principles of antenna design, the electromagnetic radiation will set up an oscillating potential difference between the first half 1, and the second half 3 of the dipole antenna. The potential difference will oscillate with the same frequency as the absorbed electromagnetic radiation. This oscillating potential difference will manifest itself across the lateral field emission diode 2 whose cathode, manifested by cathode tip 15 which is a pointed edge of the first half 1 of the antenna, is integral with the first half 1 of the antenna, and whose anode, manifested by anode surface 16 which is a nonpointed edge of the second half 3 of the antenna, is integral with the second half 3 of the antenna. The pointed edge making the cathode tip 15 is located on a part of the first half 1 of the antenna that is located closest to the second half 3 of the antenna as shown. The nonpointed edge making the anode surface 16 is located on a part of the second half 3 of the antenna that is located closest to the first half 1 of the antenna.

During the positive half cycle of the electromagnetic radiation, the second half 3 of the antenna is positive with respect to the first half 1 of the antenna, and field emission of electrons occurs off of the tip of the cathode 15. The field emitted electrons will be absorbed at the anode surface 16, causing a surplus of electrons in the second half 3 of the antenna. During the negative half cycle, the second half 3 of the antenna is negative with respect to the first half 1 of the antenna. Since the anode surface 16 is flat, it does not emit an appreciable amount of electrons and thus no field emission current flows in the negative half of the cycle. Thus, a voltage is applied to the capacitor 6, and any load 9 attached to terminals 7 and 8. This allows the surplus of electrons in the second half 3 of the antenna to flow through the attached load 9 back to the first half 1 of the antenna. The capacitor 6 smooths the voltage available at the terminals by charging from the antenna during the negative half cycle and discharging through the load 9 during the positive half cycle. This illustrates how the cathode tip 15 forming the cathode is integrally and electrically connected to the first half 1 of the antenna and how the anode is integrally and electrically connected to the second half 3 of the antenna and how a field emission diode 2 comprising the anode 16 and cathode 15 are electrically connected between the first half 1 and the second half 3 of the antenna.

In the preferred embodiment shown in FIG. 1, the rectenna is designed to rectify an electromagnetic wave having a predetermined frequency between 1,000 GHz and 10 GHz. This would require that the separation 17 between the anode and cathode be less than 10 microns, and preferably less than 3 microns.

The rectenna is not limited to a dipole antenna design, nor to the half wave rectifier described above. FIG. 3 shows a similar structure, but using a folded dipole antenna **26** instead of the simple dipole antenna. The folded dipole antenna **26** typically has a higher impedance than the simple dipole, which may make a better coupling between the antenna and the diode. The folded dipole antenna **26** could be manufactured in the same way as the embodiment shown in FIG. **1**, having the same cross-sectional view. For illustrative purposes, the folded dipole antenna shown in FIG. **3** is made using the method described in U.S. Pat. No. 4,855,636 by Busta et al. FIG. **4** is a cross-sectional view of FIG. **3** along lines **4**. In this embodiment a silicon wafer **21** is attached to a conducting layer **22**. Preferably the silicon wafer **21** has a thickness equal to approximately ¼ the wavelength of the electromagnetic radiation to be rectified. As described in U.S. Pat. No. 4,855,636 approximately 1 micron of thermal silicon dioxide is grown on the silicon wafer **21** forming a first insulating layer **25**. A conducting layer is deposited on the first insulating layer **25** to form the folded dipole antenna **26** with a first half **28** and second half **30** of the antenna and an integrated anode **25** and cathode **27**. In the preferred embodiment the length **12** of the folded dipole antenna **26** is approximately equal to L/2, where L is the wavelength of the electromagnetic radiation to be rectified. The entire structure is then covered by a layer of undoped, highly resistive polycrystalline silicon **23**. The upper surface of the polycrystalline silicon **23** is thermally oxidized to form a top insulating layer **20**. Windows are made through the top insulating layer **20** to allow the etching of a chamber **24** and holes for contacts **32** and **36**. A metallic layer is then applied over the top insulating layer **20** and then etched back to create contacts **32** and **36** and for creating a window plug **34**.

The folded dipole rectenna shown in FIGS. **3** and **4** rectifies electromagnetic waves in the same manner as the dipole rectenna described above. Using the described method of building the folded dipole rectenna, the integrated diode can be made so that the separation between the cathode tip **27** and the anode surface **25** would be in the above described range for rectifying signals with frequencies higher than 10 GHz. At an operating voltage of 500 volts it is estimated that the leakage current due to parasitic current through the undoped polycrystalline silicon layer **23** would be 500 pico Amps. This leakage could be further reduced by replacing the polycrystalline silicon side walls with silicon dioxide side walls. The integration of field emission diodes with an antenna in this embodiment provides a very efficient rectenna that can rectify signals with frequencies equal to or greater than microwaves. In addition, the provided diodes can easily handle 500 volts, wherein the Schottky barrier diodes used in the prior art had a reverse breakdown voltage of 60–70 volts.

FIG. **5** shows a rectenna with a dipole antenna, comprising a first strip of conductive material on a substrate **13** with a length along a first direction **11** less than L/2, where L is the wavelength of the electromagnetic radiation to be rectified, forming a first half **42** of the antenna and a second conductive strip on a substrate **13** with a length along the first direction **11** less than L/2 forming a second half **44** of the antenna, and a full wave bridge rectifier. The second conductive strip **44** is located along the first direction **11** with respect to the first conductive strip **42**. The rectifier utilizes four field emission diodes **46**, **48**, **50** and **52** arranged in a full wave bridge configuration. The configuration illustrated in FIG. **5** is manufactured in the same manner as the embodiment illustrated in FIG. **1**. It would also be possible for this embodiment to be manufactured in the same manner as the embodiment illustrated in FIG. **3**.

Electromagnetic radiation of wavelength L is absorbed by the dipole antenna **42** and **44**. According to well known principles of antenna design, incident electromagnetic radiation will set up an oscillating potential difference between the first half **42**, and the second half **44** of the dipole antenna. The potential difference will oscillate at the same frequency as the absorbed electromagnetic radiation. This oscillating potential difference will manifest itself across the lateral field emission diodes.

During the positive half cycle of the electromagnetic radiation, the second half **44** of the antenna is positive with respect to the first half **42** of the antenna, and field emission of electrons occurs off of the tip of a cathode tip **54** of a first diode **48**, wherein the cathode tip **54** is an integral part of the first half **42** of the antenna formed by a pointed edge of the first strip of conductive material which forms the first half **42** of the antenna. The field emitted electrons will be absorbed at the anode surface **56** of the first diode **48**, which is formed by a nonpointed edge of a third strip of conductive material forming an anode terminal **70**, causing a surplus of electrons in the anode terminal **70**. Also during the positive half cycle of the electromagnetic radiation, field emission of electrons occurs off of the tip of cathode **58** of a second diode **46**, wherein the cathode tip **58** is formed by a pointed edge of a fourth strip of conductive material on the substrate **13**, wherein the fourth strip of conductive material forms a cathode terminal **72**. The field emitted electrons will be absorbed at the anode surface **60** of the second diode **46**, wherein the anode surface **60** is an integral part of the second half **44** of the antenna, causing a surplus of electrons in the second half **44** of the antenna. During the negative half cycle, the second half **44** of the antenna is negative with respect to the first half **42** of the antenna, and field emission of electrons occurs off of the tip of the cathode tip **62** of a third diode **50**, wherein the cathode tip **62** is an integral part of the second half **44** of the antenna. The field emitted electrons will be absorbed at the anode surface **64** of the second diode **50**, which is part of the anode terminal **70**, causing a surplus of electrons in the anode terminal **70**. Also during the negative half cycle of the electromagnetic radiation, field emission of **5** electrons occurs off of the tip of cathode **66** of a fourth diode **52**, wherein the cathode tip **66** is part of the cathode terminal **72**. The field emitted electrons will be absorbed at the anode surface **68** of the fourth diode **52**, wherein the anode surface **68** is an integral part of the first half **42** of the antenna, causing a surplus of electrons in the first half **42** of the antenna.

Thus, during the full wavelength electrons flow from the cathode terminal **72** to either the first **42** or second **44** half of the antenna and then to the anode terminal **70**. The surplus of electrons gathered at the anode terminal **70** can flow through the negative load terminal **74** electrically connected to the anode terminal and then through a load to a positive load terminal **76** electrically connected to the cathode terminal **72**. The anode terminal **70** acts as an anode for both the first part **42** of the antenna and the second part **44** of the antenna, and the cathode terminal **72** acts as a cathode for both the first part **42** of the antenna and the second part **44** of the antenna. Although a capacitor is not needed, it may be used to smooth the current flow between terminals **74**, **76**.

In the preferred embodiment of the invention, the total length **140** of the first half **42** and the second half **44** of the antenna along the first direction **11** is approximately equal to L/2. As shown in FIG. **5**, the four rectifying field emission diodes are electrically connected between the first half **42** and the second half **44** of the antenna making two parallel sets of two diodes in series.

An advantage of the invention is that a large number of rectennas could be inexpensively combined in an array using conventional semiconductor manufacturing techniques. FIGS. **6** and **7** illustrate different arrays of rectennas. FIG. **6** shows a parallel array of the half wave rectennas shown in FIG. **1**. For clearer illustration of the embodiment, only the pattern of conductive strips is shown. Each half wave rectenna in the array has a first half **80** and a second half **82** of an antenna. Each first half **80** of an antenna has an integrally connected cathode tip **84**. Each second half **82** of an antenna has an integrally connected anode surface **86**. Each first half **80** of an antenna is electrically connected to a first load terminal **85** and a first half of a capacitor **87**. Each second half **82** of an antenna is electrically connected to a second load terminal **86** and a second half of the capacitor **87**. Each individual rectenna would function like the rectenna embodiment illustrated in FIG. **1**. Attaching them in a parallel configuration as illustrated would increase the current available at the terminals.

FIG. **7** shows a series array of the full wave rectennas shown in FIG. **5**. For clear illustration only the pattern of conductive strips is shown. The array comprises a first terminal **92** electrically connected to a first load terminal **94**. The electromagnetic signal to be rectified will cause electrons to flow from the first terminal **92** to the first half **96** of a first antenna and the second half **98** of the first antenna. The electromagnetic signal will also cause electrons to flow from the first half **96** of the first antenna and the second half **98** of the first antenna to a second terminal **100**. The second terminal **100** acts as an anode terminal to the first antenna. The electromagnetic signal will cause electrons to flow from the second terminal **100** to the first half **102** of a second antenna and the second half **104** of the second antenna. The electromagnetic signal will also cause electrons to flow from the first half **102** of the second antenna and the second half **104** of the second antenna to a third terminal **106**. The second terminal **100** acts as a cathode terminal to the second antenna, and the third terminal **106** acts as an anode terminal to the second antenna. The electrons continue to flow through the subsequent antenna elements and terminals until they reach a final terminal **108**, which is electrically connected to a second load terminal **110**. This series configuration will increase the voltage across the first **94** and second **110** load terminals.

In either the parallel or the series configurations, an external capacitor could be connected to the load terminals.

In addition to the lateral diode shown so far, a vertical field emission diode can also be used as the rectifier in a rectenna. FIGS. **8** and **9** show a half wave rectenna using a half wave vertical field emission diode **116** and a dipole antenna with a first half **112** and a second half **114**. The vertical field emission diode comprises an insulator **118** placed on the first half **112** of the antenna. In a hole **113**, formed in the insulator, a conductive cone or pyramid **120** is formed in electrical contact with the first **112** half of the antenna. A conducting cap **122** is placed over the hole **113**, that also makes electrical contact with the second half **114** of the antenna. The hole **113** can be evacuated and sealed, forming an integral vacuum diode. In operation this embodiment works in the same manner as the embodiment illustrated in FIGS. **1** and **2**, except that the vertical diode causes the electrons to be emitted vertically off of the tip of the cone or pyramid **120** instead of horizontally off of the point. The manufacturing of vertical field emission diodes is described in U.S. Pat. No. 4,721,885 by Brodie, and U.S. Pat. Nos. 3,755,704 and 3,789,471 by Spindt incorporated by reference.

The foregoing description of preferred embodiments of the invention have been presented for purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed, and obviously many modifications and variations are possible in light of the above teaching. The embodiments were chosen and described in order to best explain the principles of the invention and its practical application to thereby enable others skilled in the art to best utilize the invention in various embodiments and with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the claims appended hereto.

We claim:

1. A rectifying antenna for rectifying electromagnetic radiation with a wavelength shorter than 3.0 centimeters, comprising:

an antenna having a first half and a second half; and

a first field emission diode for rectifying a current flow, wherein the first field emission diode has a first anode and first cathode electrically connected between the first half of the antenna and the second half of the antenna, and wherein the first cathode is separated from the first anode by a distance of less than 10 microns and wherein the antenna has a length which is approximately equal to half of the wavelength of the electromagnetic radiation to be rectified.

2. A rectifying antenna as claimed in claim **1**, further comprising:

a first load terminal electrically connected to the first half of the antenna; and

a second load terminal electrically connected to the second half of the antenna, and wherein the first cathode is electrically connected to the first half of the antenna, and the first anode is electrically connected to the second half of the antenna.

3. A rectifying antenna as claimed in claim **2**, wherein the first cathode is integral with the first part of the first antenna, and wherein said first cathode comprises a pointed edge of the first part of the antenna, and wherein the first anode is integral with the second part of the antenna, and wherein the first anode comprises a nonpointed edge of the second part of the antenna.

4. A rectifying antenna as claimed in claim **2**, wherein the first field emission diode is a linear field emission diode.

5. A rectifying antenna as claimed in claim **2**, wherein the first field emission diode is a vertical field emission diode.

6. A rectifying antenna as claimed in claim **1**, further comprising:

a first terminal, wherein the first field emission diode is electrically connected between the first terminal and the second half of the antenna with the first anode being electrically connected to the first terminal and the first cathode being electrically connected to the second half of the antenna;

a second terminal;

a second field emission diode with a second cathode and second anode electrically connected between the first terminal and the first half of the antenna with the second anode being electrically connected to the first terminal and the second cathode being electrically connected to the first half of the antenna;

a third field emission diode with a third cathode and a third anode electrically connected between the second terminal and the first half of the antenna with the third anode being electrically connected to the first half of the antenna and the third cathode being electrically connected to the second terminal; and

a fourth field emission diode with a fourth cathode and a fourth anode electrically connected between the second terminal and the second half of the antenna with the fourth anode being electrically connected to the second half of the antenna and the fourth cathode being electrically connected to the second terminal.

7. A rectifying antenna as claimed in claim 6, wherein the first cathode is formed by a pointed edge of the second half of the antenna, and wherein the second cathode is formed by a pointed edge of the first half of the antenna, and wherein the first and second anodes are formed by nonpointed edges of the first terminal, and wherein the third anode is formed by a nonpointed edge of the first half of the antenna, and wherein the fourth anode is formed by a nonpointed edge of the second half of the antenna, and wherein the third and fourth cathodes are formed by pointed edges of the second terminal.

8. A rectifying antenna as claimed in claim 6, wherein the field emission diode is a lateral field emission diode.

9. A rectifying antenna for rectifying electromagnetic radiation with a wavelength shorter than 3.0 centimeters, comprising:

a substrate comprising a layer of insulating material;

a first cathode;

a first anode;

a first conductive strip on the substrate, with a length in a first direction, wherein the first conductive strip is integrally and electrically connected to the first cathode;

a second conductive strip on the substrate, with a length in the first direction, wherein the second conductive strip is integrally and electrically connected to the first anode, and wherein the second conductive strip is located along the first direction with respect to the first conductive strip, and wherein the length of the first conductive strip in the first direction is less than half of the wavelength and wherein the length of the second conductive strip in the first direction is less than half of the wavelength, and wherein the length of the first conductive strip in the first direction summed with the length of the second conductive strip in the first direction make a sum which is approximately equal to half of the wavelength;

a first load terminal electrically connected to the first conducting strip; and

a second load terminal electrically connected to the second conducting strip, wherein the first cathode is located on the part of the first conductive strip closest to the second conductive strip, and wherein the first anode is located on the part of the second conductive strip closest to the first cathode, and wherein the first anode and the first cathode are separated by a distance less than 10 microns forming a first field emission diode.

10. A rectifying antenna as claimed in claim 9, wherein the cathode is formed by a pointed edge of the first conductive strip, and wherein the anode is formed by a nonpointed edge of the second conductive strip.

11. A rectifying antenna as claimed in claim 9, wherein the first field emission diode is a vertical field emission diode.

12. A rectifying antenna for rectifying electromagnetic radiation with a wavelength shorter than 3.0 centimeters, comprising:

a substrate comprising a layer of insulating material with a first surface;

a first conductive strip on a first surface of the substrate with a length in a first direction wherein a pointed edge of the first conductive strip forms a cathode of a linear field emission diode; and

a second conductive strip on the first surface of the substrate with a length in the first direction wherein the second conductive strip forms an anode of a linear field emission diode, and wherein the second conductive strip is located along the first direction with respect to the first conductive strip, and wherein the length of the first conductive strip in the first direction is less than half the wavelength, and wherein the length of the second conductive strip in the first direction is less than half the wavelength and wherein the length of the first conductive strip in the first direction summed with the length of the second conductive strip in the first direction make a total length which is approximately equal to half of the wavelength.

13. A rectifying antenna as claimed in claim 12, further comprising a conductive layer on a second surface of the substrate, wherein the conductive layer is separated from the first conductive strip by a distance which is approximately equal to one fourth of the wavelength.

14. A rectifying antenna as claimed in claim 13, further comprising:

a first load terminal electrically connected to the first conductive strip; and

a second load terminal electrically connected to the second conducting strip, wherein the cathode is located on the part of the first conductive strip closest to the second conductive strip, and wherein the anode is located on the part of the second conductive strip closest to the cathode, and wherein the first anode and the first cathode are separated by a distance less than 10 microns forming a field emission diode.

15. A rectifying antenna as claimed in claim 13, further comprising:

a third conductive strip on the first surface of the substrate with first and second nonpointed edges that form first and second anodes, wherein a pointed edge of the second conductive strip forms a cathode, and the first anode of the third conductive strip is located less than 10 microns away from the cathode on the first conductive strip forming a first field emission diode and the second anode of the third conductive strip is located less than 10 microns away from the cathode on the second conductive strip forming a second field emission diode; and

a fourth conductive strip on the first surface of the substrate with first and second pointed edges that form first and second cathodes, wherein a non-pointed edge of the first conductive strip forms an anode, and the first cathode of the fourth conductive strip is located less than 10 microns away from the anode on the first conductive strip forming a third field emission diode and the second cathode of the fourth conductive strip is located less than 10 microns away from the anode on the second conductive strip forming a fourth field emission diode.

[57] **ABSTRACT**

A superconducting laminate having at least one layer of metal and at least one layer of superconducting material. The metal layer and the superconducting layer are bonded. The metal later may also include carbon fibers from various precursors. The superconductor may be a composite material. The invention also includes a method of making the laminates.

SUPERCONDUCTOR-METAL LAMINATES AND METHOD OF MAKING

BACKGROUND OF THE INVENTION

The present invention relates to superconductor-metal laminates and to a method of making such laminates.

The high T_c (superconducting transition temperature) superconductors are generally brittle, hard to shape, and high in electrical resistivity at normal temperatures. By high T_c superconductors are meant superconductors with T_c above the temperature of liquid nitrogen (77° K.). Typically, metals are not high T_c superconductors and at normal temperatures are ductile, formable, low in electrical resistivity and high in thermal conductivity.

It has been recognized that the combination of a high T_c superconductor and a metal in the form of a composite material is attractive for the following reasons: the combination has improved toughness, ductility, shapeability and formability; improved electrical and thermal stabilization; and improved critical current density. The critical current density is the current density above which the superconductor loses its superconductivity, at a given temperature below T_c.

Powder metallurgy has been used to fabricate superconductor-metal composites. (In-Gann Chen, S. Sen and D. M. Stefanescu, Appl. Phys. Lett. 52 (16), 1355 (1988); F. H. Streitz, M. Z. Cieplak, Gang Xiao, A. Gavrin, A. Bakhshai and C. L. Chien, Appl. Phys. Lett. 52, 927 (1988); A. Goyal, P. D. Funkenbusch, G. C. S. Chang and S. J. Burns, Mater. Lett. 6 (8-9), 257 (1988)). Generally powder metallurgy involves mixing superconductor powder and metal powder, followed by sintering the mixture. There are some problems with this method. For example, the metal content is limited to 50 vol. % or below in order to have a continuous superconducting path in the composite. This limits the ductility of the composite. In addition, the choice of metal is limited to metals that are stable at the sintering temperature in oxygen and do not react with the superconductor at the sintering temperature (typically 950° C. for $YBa_2Cu_3O_{7-\delta}$).

Another method that has been used in forming a superconductor-metal composite involves (i) packing a superconductor powder in a metal tube, (ii) drawing the tube to a smaller diameter, and (iii) sintering. This method is commonly known as the metal tube drawing method. (R. W. McCallum, J. D. Verhoeven, M. A. Noack, E. D. Gibson, F. C. Laabs and D. K. Finnemore, Advanced Ceramic Materials 2 (3B), 388 (1987); S. Jin, R. C. Sherwood, R. B. Van Dover, T. H. Tiefel and D. W. Johnson, Jr., Appl. Phys. Lett. 51, 203 (1987)). Similar drawbacks as with the powder metallurgy method have been recognized with this method. For example, the choice of metal is limited to metals that are stable at the high sintering temperature required by the superconductor.

A further disadvantage of the superconductor-metal composites formed by the above described methods is that they are generally weak in tension.

It is therefore an object of this invention to provide a method for fabricating superconductor-metal materials which overcome the problems recognized in the art.

It is a further object to provide a method of producing a superconductor-metal material which overcomes the limitations of known methods while retaining the desirable characteristics.

A still further object is to produce a superconductor-metal material having both good tensile and compressive strength.

SUMMARY OF THE INVENTION

The invention is a superconducting laminate comprising, first and second layers; said first layer comprising a ceramic superconductor and said second layer comprising a metal; said first layer being diffusion bonded to said second layer.

The invention further comprises a superconducting laminate comprising first and second layers; said first layer comprising a ceramic superconductor and said second layer comprising a metal and carbon fibers; said first layer being bonded to said second layer.

The invention also comprises a method for preparing a superconducting laminate comprising the steps of, a) preparing a superconducting layer; b) preparing a metal layer; and c) diffusion bonding said superconducting layer with said metal layer.

The invention includes a method for preparing a superconducting laminate comprising the steps of, a) preparing a superconducting layer; b) preparing a metal-carbon fiber layer; and c) bonding said superconducting layer with said metal-carbon fiber layer.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 Is an SEM (Scanning Electron Microscope) photograph of a portion of a polished section of an MMC-$YBa_2Cu_3O_{7-\delta}$-MMC (MMC is the metal-matrix carbon fiber composite) three-layer laminate containing 32.1 vol. % fiber and 50.2 vol. % Sn (Tin). The left half is the MMC, the right half is the superconductor. The small dumbbell shaped spots in the MMC are the tips of carbon fibers.

FIG. 2 Shows the dependence of the electrical resistivity on temperature for the plain superconductor (solid circles), for a laminate containing 80.1% vol. % Sn and no fibers (open circles), and for a laminate containing 32.1 vol. % fibers and 50.2 vol. % Sn (crosses).

FIG. 3 Shows the compressive stress-strain curves (up to fracture) for a laminate without fibers (24 vol. % Sn) (open circles) and a laminate with fibers (51.1 vol. % Sn and 26.2 vol. % fibers) (solid circles).

FIG. 4 Illustrates the effect of tin content on the compressive ductility of laminate without carbon fibers; error bar of ±7%.

FIG. 5 Shows the effects of tin and fiber contents on the compressive ductility; error bar of ±5%.

FIG. 6 Is an SEM photograph of the compressive fracture surface of a laminate containing 19.5 vol. % Sn and no fibers. The right one-third of the photograph is tin, the left two-thirds of the photograph is the superconductor.

FIG. 7 Shows the effects of tin and fiber contents on the compressive elastic modulus; error bar of ±8%.

FIG. 8 Shows the effects of tin and fiber contents on the compressive strength; error bar of ±9%.

FIG. 9 Shows the tensile stress-strain curves (up to fracture) for a laminate without fibers (24 vol. % Sn) (open circles) and a laminate with fibers (51.4 vol. % Sn and 27.2 vol. % fibers) (solid circles).

FIG. 10 Illustrates the effects of tin and fiber contents on the tensile strength; error bar of ±8%.

FIG. 11 Illustrates the effects of tin and fiber contents on the tensile ductility; error bar of ±5%.

FIG. **12** Shows the effects of tin and fiber contents on the tensile modulus; error bar of ±7%.

FIG. **13** Shows the dependence of the tensile strength on the carbon fiber content in vol. % fibers, (the volume of the superconductor is not counted in calculating the volume % fibers). Circles: without superconductor (MMC alone), error bar of ±9%; crosses: with superconductor, error bar of ±9%.

FIG. **14** Depicts the dependence of the tensile modulus on the carbon fiber content in vol. % fibers, (the volume of the superconductor is not counted in calculating the volume % fibers). Circles: without superconductor (MMC alone), error bar of ±8%; crosses: with superconductor, error bar of ±7%.

FIG. **15** Shows the dependence of the tensile ductility on the carbon fiber content in vol. % fibers, (the volume of the superconductor is not counted in calculating the volume % fibers). Circles: without superconductor (MMC alone), error bar of ±6%; crosses: with superconductor, error bar of ±5%.

FIG. **16** Shows the dependence of the electrical resistivity on temperature for a laminate, containing 50.2 vol. % Sn and 31.0 vol. % fibers, that has been subjected to tension up to a stress of 90.6 MPa and a strain of 0.91%.

DETAILED DESCRIPTION OF THE INVENTION

By superconducting laminate is meant an article having at least 2 layers, at least one of which comprises a high T_c superconductor and at least one of which comprises a metal.

A metal as used herein means any metal which will be able to diffuse into the surface of the superconducting layer at a temperature lower than the degradation temperature of the superconducting material, and includes alloys. Examples of suitable metals include, but are not limited to tin, indium, and tin-lead alloy. A preferred metal is tin (Sn). The metal may be in a form suitable for forming the laminates of the present invention and includes foils, ingots, sheets, and powders. The thickness of the metal layer may vary in accordance with the invention, preferably, the thickness of the metal where no carbon fibers are incorporated is between about 0.1 mm to about 6 mm. The thickness of the metal layer where carbon fibers are incorporated is between about 0.4 mm to about 6 mm.

In accordance with this invention, the laminates may comprise between about 1 to about 99 vol. % metal (total volume being the volume of metal and the volume of superconductor). Preferred laminates comprise between about 40 to about 80 vol. % metal. Most preferred laminates comprise about 80 vol. % metal. Although the preferred and most preferred laminates are discussed above, the actual vol. % of the metal utilized will also depend on the thickness of the superconductor layer.

Superconductor as used herein is any ceramic superconductor and may include superconductor composites. Examples of superconductors are $YBa_2Cu_3O_{7-\delta}$, $Bi_2Sr_{3-x}Ca_xCu_2O_{8+y}$, and $Tl_2Ba_2CaCu_2O_\delta$. A preferred superconductor is $YBa_2Cu_3O_{7-\delta}$. The superconductor can be in bulk, wire or film form as prepared by any known technique. For example, for the superconductor $YBa_2Cu_3O_{7-\delta}$, the $YBa_2Cu_3O_{7-\delta}$ powder (commercially available from a variety of sources known to those skilled in the art) was pressed at a pressure of 137 MPa (mega pascal) and then sintered at 950° C. for 12 h, followed by annealing at 420° C. in flowing oxygen for 1 h. Superconductor composites include composites which comprise superconductor and metal and includes those which may be formed by the powder metallurgy method, the metal tube drawing method or other known methods. Generally, laminates having a superconducting layer in the order of at least 1000 angstroms in thickness are preferred.

The laminates of the present invention have a continuous superconducting path and the superconducting layer retains it's high T_c superconducting property after incorporation into the laminate.

While various lamination methods may be used, the laminates are preferably formed by diffusion bonding, e.g. by hot pressing the superconducting material and the metal, in air at a temperature lower than the melting point of the metal (which melting point, in accordance with this invention, is lower than the degradation temperature of the superconductor). Diffusion bonding as used herein means the solid state bonding of two materials by using heat and pressure. The degradation temperature of the superconducting material means the temperature above which the material no longer is a high T_c superconductor. For example, for the superconductor $YBa_2Cu_3O_{7-\delta}$, the degradation temperature is about 300° C., and hot pressing would be conducted at a temperature lower than 300° C.

Hot pressing is for a sufficient time and at a sufficient pressure for diffusion bonding to occur. For a given metal, the temperature, pressure and time may be adjusted so that various combinations of temperature, pressure and time may be utilized to achieve the diffusion bond. As is well known in the art, typically, if a higher temperature is used, a lower pressure and shorter time may be sufficient. The pressure utilized, however, is limited by the compressive strength of the superconductor.

In another embodiment of the invention, a laminate having three layers may be prepared. The superconductor may have a metal layer on either side of the superconductor to package the superconductor. This laminate may be prepared as described above by hot pressing a layer of superconductor sandwiched by two layers of metal, one on either side of the superconductor at a temperature below the melting point of the metal at a sufficient pressure and for a sufficient time in order to achieve diffusion bonding.

It is within the scope of this embodiment that the two metal layers on either side of the superconductor layer may comprise the same or different metals. More particularly, both layers may be tin or one metal layer may be tin and the other metal layer may be a tin-lead alloy or indium or any other combination, which would meet the above discussed parameters.

It is also within the scope of this invention to have a plurality of ceramic superconductor layers alternating with metal layers.

In another embodiment of the invention, a reinforced laminate having greater tensile strength was made by the addition of carbon fibers to the metal layer. The carbon fiber reinforced metal provides an effective way of packaging ceramic superconductors so that the package exhibits good mechanical, electrical and thermal properties. The carbon fibers may include those made from a variety of precursors such as textile fibers, pitch or other precursors. An example of a textile fiber is PAN (polyacrylonitrile).

The fibers may be in a continuous or short form. If the continuous form is used, they may be unidirectional, multidirectional or in the form of a woven fabric. In a preferred embodiment, continuous, unidirectional carbon fibers may be utilized. Between about 0 vol. % to about 50 vol. % of carbon fiber (the volume being the volume of metal and carbon fiber) may be incorporated into the metal layer. It is preferred that about 15–40 vol. % of carbon fiber is incorporated into the metal layer.

The carbon fiber reinforced metal-superconductor laminate may be prepared by using a two-step process. The first step is the preparation of a metal-matrix carbon fiber composite (abbreviated MMC) by laying up carbon fibers and metal in the form of alternate layers and consolidating by hot pressing (by using a hydraulic press or other known methods) at a temperature, pressure and time which will allow the metal to penetrate or diffuse into void spaces between the carbon fibers. The second step involves hot pressing a layer of superconductor sandwiched by two layers of MMC at a sufficient temperature, preferably below below the melting point of the metal, and at a sufficient pressure for a sufficient time in order to achieve bonding between the MMC and the superconductor. Bonding means the liquid or solid state joining of two or more materials. Methods of bonding, as used herein, includes adhesive bonding, soldering, brazing, welding and diffusion bonding.

It is to be understood, particularly in the case of carbon fiber containing materials, that lamination or bonding methods other than diffusion bonding may be used. Such methods, however, may have serious disadvantages related to physical limitations of certain materials which may allow degradation or destruction of such materials, as a result of the conditions encountered during lamination.

EXAMPLES

EXAMPLE 1

To make a superconductor-tin laminate (without carbon fibers), in accordance with this invention, the superconductor $YBa_2Cu_3O_{7-\delta}$ was prepared as described above, tin foil (60 vol. %, 4.12 g, 3.36 mm thick, includes both tin layers) was diffusion bonded to both sides of the $YBa_2Cu_3O_{7-\delta}$ superconductor layer (40 vol. %, 1.54 g, 2.24 mm thick) by hot pressing in air at 140° C. and 5.3 MPa for 15 minutes. Table 1 below lists other percentages of tin which were used and the various thicknesses of the tin (includes both layers) and the superconductor.

TABLE 1

Vol. % Sn	Thickness (mm) Superconductor	Thickness (mm) Tin
81.6	0.460	2.032
77.8	0.580	2.032
73.4	0.741	2.032
64.5	1.126	2.032

10.7	2.381	0.254
6.1	3.897	0.254

EXAMPLE 2

To produce a carbon fiber reinforced tin-superconductor laminate in accordance with this invention, the previously described two-step process may be utilized.

In the first step, a tin-matrix unidirectional carbon fiber composite (abbreviated MMC), was prepared by laying up carbon fibers (15 vol. %, 0.285 g; continuous, unidirectional, and PAN-based, which are commercially available) and tin foils (50 vol. %, 3.75 g) in the form of alternate layers and consolidating by hot pressing (by using a hydraulic press) at 244° C. and at a pressure of 64 MPa for 20 min. The thickness of the MMC layer was 4.06 mm. In the second step a layer of superconductor $YBa_2Cu_3O_{7-\delta}$ (35 vol. %. 1.21 g, 2.18 mm thick) sandwiched by two layers of MMC was hot pressed at 180° C. and 5.1 MPa for 15 min in order to achieve diffusion bonding. Note that 170° C. is below the melting point of tin (232° C.).

TEST RESULTS OF THE LAMINATES

In the resulting laminate, tin served as the adhesive and to increase the ductility, the normal-state electrical conductivity and the thermal conductivity. Carbon fibers served to increase the strength and the modulus, both in tension along the fiber direction and in compression perpendicular to the fiber layers, and also served to increase the thermal conductivity and the thermal fatigue resistance, as shown in table 2 below. Volume % as used in Table 2 includes the volume of carbon, metal and superconductor.

TABLE 2

Thermal fatigue due to cycling between room temperature and liquid nitrogen temperature

Carbon fiber Content (vol. %)	Sn content (vol. %)	No. of cycles for delamination to start*
0	43.2	63
3.0	39.4	86
8.3	40.1	102
12.0	43.1	116
15.3	48.3	123
20.1	50.2	127

*Each number is the average of three specimens.

Laminates of various fiber contents were subjected to thermal cycling between room temperature and liquid nitrogen temperature (77° K.) by immersion in liquid nitrogen for 20 min, followed by room temperature equilibration for at least 30 min, and repeating. After every cycle, each specimen was observed under an optical microscope to look for delamination (slight cracking) between the superconductor and the MMC. Table 2 shows the number of cycles for the start of delamination for each laminate composition. The higher the carbon fiber content, the greater the number of cycles required for the start of delamination.

The fabrication of the laminates, according to this invention involves relatively low temperatures. The simplicity of this process makes it possible for an operation to be set up for fabricating continuous superconducting cables which are both shielded and toughened by metal and strengthened by carbon fibers.

The toughness was measured by carrying out the Izod Test using a Tinius Olsen plastic impact tester. The toughness was 3.25 in.lb for a laminate containing 18.8 vol. % Sn (no fibers) and was 5.50 in.lb for a laminate containing 25.5 vol. % Sn (no fibers). Hence, the tin greatly enhanced the toughness.

As can be seen from the SEM photograph shown in FIG. **1**, no void or crack was observed between the MMC and the superconductor or between the tin and the carbon fibers in the MMC.

Electrical resistivity of the laminates can be seen in FIG. **2**. The electrical resistivity was measured with the four-probe technique by using a Keithley 181 nanovolt meter and a Keithley 224 programmable current source, such that the current was around 10^{-3} amperes. A thermocouple was placed so that it almost touched the sample. In the case of laminates containing fibers, the electrical resistivity was measured in the direction of the fibers however, the electrical resistivity in the direction perpendicular to the fiber axis was comparable to that in the direction parallel to the fibers. The drop to zero resistivity is slightly less sharp for either laminate than the plain superconductor. Carbon fibers have a lower electrical resistivity than the plain superconductor above T_c, but its value is higher than that of tin. Therefore, the normal-state electrical resistivity of the laminate with tin and fibers is lower than that of the plain superconductor and higher than that of the laminate with tin and no fiber.

Mechanical testing was performed using a hydraulic Materials Testing Systems (MTS). The strain in tensile or compressive testing was measured by the displacement of the crosshead. The gage length was 34.7 mm for tensile testing and 6 mm for compressive testing. Compressive testing was performed with the force perpendicular to the laminate layers. Tensile testing was performed with the force parallel to the fibers in the plane of the laminate. At least three samples were run and the data were averaged for each composition in each type of test.

FIG. **3** shows the compressive stress-strain curves (up to fracture) for a laminate containing tin (24 vol. % Sn) but no fibers (open circles) and a laminate containing 51.1 vol. % Sn and 26.2 vol. % fibers (solid circles).

FIG. **4** shows that tin greatly increases the ductility of the laminate. FIG. **5** shows that tin greatly increased the ductility of the laminate, but the fibers decreased the ductility.

As can be seen in FIG. **6**, cracks are observed to extend from the tin superconductor interface inward into the superconductor. A similar fracture is observed in a laminate with both fibers and tin. In contrast, the plain superconductor (without tin or fiber) shatters and disintegrates into particles upon fracture. Hence, the fracture behavior is dramatically different between either laminate and the plain superconductor.

The decrease of the modulus with increasing tin content and decreasing fiber content is significant and can be seen in FIG. **7**. No systematic trend can be seen in FIG. **8** in the compressive strength, because the strength is very sensitive to small flaws that are bound to be present in the superconductor.

FIG. **9** shows the tensile stress-strain curves (up to fracture) for a laminate containing tin (24 vol. % Sn) but no fibers (open circles) and a laminate containing 51.4 vol. % Sn and 27.2 vol. % fibers (solid circles).

FIGS. **10**, 11 and 12 show the effects of tin and fiber contents on the tensile test results. The tensile test was performed along the fiber direction. The addition of carbon fibers greatly improved the tensile strength (FIG. **10**), but decreased the ductility slightly (FIG. **11**). The tensile modulus was increased by increasing the fiber content. Debonding between the MMC and the superconductor and some fiber pull-out were observed from the fracture surface after the tensile test.

FIGS. **13**, **14** and **15** show the effects of the superconductor on the tensile test results. Data obtained with the presence of the superconductor (in the form MMC-superconductor-MMC) are shown by circles. Data obtained with the absence of the superconductor (i.e., MMC alone) are shown by crosses. The horizontal scale of FIGS. **13**, 14 and 15 show the vol. % fibers such that the volume of the superconductor was not counted in the volume of the laminate. (Note that this scale is different from the horizontal scale of FIGS. **4**, **5**, **7**, **8**, **10**, **11** and **12** in which the volume of the superconductor was counted in calculating the volume percent fibers.) The similarity of data with and without the superconductor in FIGS. **13** and **14** shows that the tensile load was almost totally sustained by the MMC. FIG. **15** shows that the tensile ductility is somewhat diminished by the presence of the superconductor.

The tensile test for the plain superconductor (without tin or fibers) did not give very reliable results because of the difficulty of gripping the superconductor, which was difficult in the absence of tin. Nevertheless, the tensile strength was about 5.2 MPa, the tensile modulus was roughly 1.3 GPa (Giga pascal), and the tensile ductility was roughly 0.5%.

A laminate containing 31.0 vol. % fibers and 50.2 vol. % tin was subjected to tension up to a tensile stress of 90.6 Mpa and a tensile strain of 0.91% (below the stress or strain required for fracture) and then the load was released (allowing the strain to return to essentially zero) and the electrical resistivity was measured as a function of temperature, as shown in FIG. **16**. It remained superconducting.

Comparison of FIG. **8** and **10** shows that, without fibers, the tensile strength (parallel to the fiber direction) was much less than the compressive strength (perpendicular to the fiber layers), but with about 24 vol. % fibers, the tensile strength was approximately equal to the compressive strength. With further increase of the fiber content, the tensile strength exceeded the compressive strength.

The tensile strength of the plain superconductor was roughly 5.2 MPa. The presence of tin (without fibers) increased the value to about 20 MPa (FIG. **10**). Further addition of carbon fibers significantly increased the tensile strength, up to 134 MPa for 31 vol. % fibers.

Carbon fibers increased the compressive strength, compressive modulus, tensile strength and tensile modulus, but they decreased the compressive ductility and tensile ductility. However, because tin was also present and tin is a soft metal, the compressive ductility for the case of 31 vol. % fibers was approximately equal to that for the plain superconductor (without tin or fiber). For carbon fiber contents less than 30 vol. % fibers, the compressive ductility exceeded that of the plain superconductor. In general, the carbon fibers decreased the tensile ductility (FIG. **11**) much less than the compressive ductility (FIG. **6**).

FIG. **16** and **11** show that the superconducting behavior of the laminates was maintained after tension almost to the point of tensile fracture.

The fabrication of the laminates involved low temperatures. The simplicity of this process makes it possible for an operation to be set up for fabricating continuous superconducting cables which are both shielded and toughened by tin and strengthened by carbon fibers. In contrast to powder metallurgy, the diffusion bonding method allows the metal to be the major phase while still maintaining a continuous superconducting path in the laminate. Furthermore, carbon fibers, with their nearly zero thermal expansion coefficient helps match the thermal expansion coefficients of the MMC layer and the superconductor layer. This matching is necessary in order to enhance the durability of the composite to thermal cycling (i.e. thermal fatigue). In addition, carbon fibers are excellent in thermal conductivity (both at ambient and cryogenic temperatures), wear resistant, corrosion resistant, and are low in electrical resistivity.

Other embodiments of the invention will be apparent to the skilled in the art from a consideration of this specification or practice of the invention disclosed herein. It should be understood that there may be other embodiments which fall within the spirit and scope of the invention as defined by the following claims.

What is claimed is:

1. A superconducting laminate comprising first and second layers; said first layer comprising a high T_c ceramic superconductor and said second layer comprising a metal; said first layer being diffusion bonded to said second layer, wherein said metal is selected from the group consisting of tin, indium and tin lead alloy.

2. The laminate as recited in claim **1** further comprising a third layer, said third layer being adjacent to and being diffusion bonded to a second side of said superconducting layer such that the first layer is adjacent to the first side of said superconducting layer.

3. A superconducting laminate comprising first and second layers; said first layer comprising a high T_c ceramic superconductor and said second layer comprising a metal and carbon fiber; said first layer being diffusion bonded to said second layer, wherein said metal is selected from the group consisting of tin, indium and tin lead alloy.

4. The laminate as recited in claim **1** wherein the superconductor is selected from the group consisting of $YBa_2Cu_3O_{7-\delta}$, $Bi_2Sr_{3-x}Ca_xCu_2O_{8+y}$, and $Tl_2Ba_2CaCu_2O_8$.

5. The laminate as recited in claim **2** wherein the superconductor is selected from the group consisting of $YBa_2Cu_3O_{7-\delta}$, $Bi_2Sr_{3-x}Ca_xCu_2O_{8+y}$, and $Tl_2Ba_2CaCu_2O_8$.

6. The laminate as recited in claim **4** wherein the superconductor is $YBa_2Cu_3O_{7-\delta}$.

7. The laminate as recited in claim **5** wherein the superconductor is $YBa_2Cu_3O_{7-\delta}$.

8. The laminate as recited in claim wherein the metal is selected from the group consisting of tin, indium and tin lead alloy.

9. The laminate as recited in claim **8** wherein the metal is tin.

10. The laminate as recited in claim **2** wherein the metal is selected from the group consisting of tin, indium and tin lead alloy.

11. The laminate as recited in claim **6** wherein the metal is selected from the group consisting of tin, indium and tin lead alloy.

12. The laminate as recited in claim **7** wherein the metal is selected from the group consisting of tin, indium and tin lead alloy.

13. The laminate as recited in claim **10** wherein the second and third layers comprise the same metal.

14. The laminate as recited in claim **10** wherein the second and third layers comprise different metals.

15. The laminate as recited in claim **13** wherein the metal is tin.

16. The laminate as recited in claim **14** wherein the metals are tin and tin lead alloy.

17. The laminate as recited in claim **1** wherein the second layer further comprises carbon fibers.

18. The laminate as recited in claim **2** wherein the second layer further comprises carbon fibers.

19. The laminate as recited in claim **6** wherein the second layer further comprises carbon fibers.

20. The laminate as recited in claim **7** wherein the carbon fibers are from textile fiber precursors.

21. The laminate as recited in claim **17** wherein the carbon fibers are from textile fiber precursors.

22. The laminate as recited in claim **18** wherein the carbon fibers are from textile fiber precursors.

23. The laminate as recited in claim **19** wherein the carbon fibers are from textile fiber precursors.

24. The laminate as recited in claim **21** wherein the textile fibers are PAN based.

25. The laminate as recited in claim **22** wherein the textile fibers are PAN based.

26. The laminate as recited in claim **1** wherein the metal will be able to diffuse into the surface of the superconducting layer at a temperature lower than the degradation temperature of the superconductor.

27. The laminate as recited in claim **2** wherein the metal will be able to diffuse into the surface of the superconducting layer at a temperature lower than the degradation temperature of the superconductor.

28. The laminate as recited in claim **1** wherein the superconductor is a superconducting composite.

29. The laminate as recited in claim **2** wherein the superconductor is a superconducting composite.

30. The laminate as recited in claim **28** wherein the superconducting composite comprises a metal.

31. The laminate as recited in claim **29** wherein the superconducting composite comprises a metal.

32. The laminate as recited in claim **30** wherein said superconducting composite is fabricated by powder metallurgy.

33. The laminate as recited in claim **31** wherein said superconducting composite is fabricated by metal tube drawing.

34. The laminate as recited in claim **1** further comprising a plurality of alternating superconducting and metal containing layers.

35. The laminate as recited in claim **1** wherein the first layer comprises between about 20 to about 60 vol. % of the laminate.

36. The laminate as recited in claim **2** wherein the first layer comprises between about 20 to about 60 vol. % of the laminate.

37. The laminate as recited in claim **1** wherein the second layer comprises between about 40 to about 80 vol. % of the laminate.

38. The laminate as recited in claim **17** wherein the carbon fibers comprise between about 15–40 vol. % of said second layer.

39. The laminate as recited in claim **1** wherein the second layer is between about 0.1 mm to about 6 mm in thickness.

40. The laminate as recited in claim **35** wherein the second layer is between about 0.1 mm to about 6 mm in thickness.

41. The laminate as recited in claim **36** wherein the second layer is between about 0.1 mm to about 6 mm in thickness.

42. The laminate as recited in claim **38** wherein the second layer is between about 0.4 mm to about 6 mm in thickness.

43. The laminate as recited in claim **1** wherein the first layer is at least 1000 Angstroms in thickness.

44. The laminate as recited in claim **2** wherein the first layer is at least 1000 Angstroms in thickness.

45. The laminate as recited in claim **40** wherein the first layer is at least 1000 Angstroms in thickness.

46. The laminate as recited in claim **42** wherein the first layer is at least 1000 Angstroms in thickness.

47. A superconducting laminate comprising, first and second layers; said first layer comprising about 40 vol. % $YBa_2Cu_3O_{7-\delta}$, and being about 3.4 mm thick; said second layer comprising about 60 vol. % of tin and being about 2.3 mm thick; said first layer being diffusion bonded to said second layer at 140° C. and 5.3 MPa for about 15 minutes.

48. A superconducting laminate prepared by a process comprising the steps of:

a) preparing a high T_c superconducting layer;

b) preparing a metal layer; and

c) diffusion bonding said superconducting layer to said metal layer;

wherein said metal is selected from the group consisting essentially of tin, indium and tin lead alloy.

[57] **ABSTRACT**

A silent communications system in which nonaural carriers, in the very low or very high audio frequency range or in the adjacent ultrasonic frequency spectrum, are amplitude or frequency modulated with the desired intelligence and propagated acoustically or vibrationally, for inducement into the brain, typically through the use of loudspeakers, earphones or piezoelectric transducers. The modulated carriers may be transmitted directly in real time or may be conveniently recorded and stored on mechanical, magnetic or optical media for delayed or repeated transmission to the listener.

SILENT SUBLIMINAL PRESENTATION SYSTEM

BACKGROUND—FIELD OF THE INVENTION

This invention relates in general to electronic audio signal processing and, in particular, to subliminal presentation techniques.

BACKGROUND—DESCRIPTION OF PRIOR ART

Subliminal learning enjoys wide use today and subliminal tapes are being manufactured by a number of companies in the United States alone. Several decades of scientific study indicate that subliminal messages can influence a human's attitudes and behavior. Subliminal, in these discussions, can be defined as "below the threshold of audibility to the conscious mind." To be effective however, the subliminally transmitted information (called affirmations by those in the profession) must be presented to the listener's ear in such a fashion that they can be perceived and "decoded" by the listener's subconscious mind. We are referring to audio information in this discussion, however, information could be inputted into the subject's subconscious mind through any of the body's sensors, such as touch, smell, sight or hearing. As an example, early development work in the subliminal field utilized motion pictures and slide projections as the medium. Early research into visual and auditory subliminal stimulation effects is exemplified by U.S. Pat. Nos. 3,060,795 of Corrigan, et al. and 3,278,676 of Becker. U.S. Pat. No. 4,395,600 of Lundy and Tyler is representative of later developments in today's subliminal message techniques.

The majority of the audio subliminal tapes available today are prepared using one basic technique. That is, the verbal affirmations are mixed with, and recorded at a lower level than, a "foreground" of music or sounds of ocean surf or a bubbling mountain brook or other similar "masking" sounds. The affirmations are generally recorded 5 decibels (db) or so below the "foreground" programming and regenerative automatic gain control is usually applied to permit the affirmations to change their recorded amplitude in direct proportion to the short term averaged amplitude of the continually varying "foreground" material. In other words, the volume of the affirmations will follow or track the volume changes of the "foreground" programming, but at a lower volume level. Circuit provisions are also usually included to "gate" the affirmations off when the music amplitude is low or zero. This insures that the affirmations cannot be heard during quiet program periods. Thus, today's subliminal affirmations can be characterized as being "masked" by music or other sounds, of constantly changing amplitude and of being reduced or cut off entirely during periods of low or quiet "foreground" programming.

One of the principal, and most widely objected to, deficiencies in available subliminal tape presentation techniques is that the presence of the "foreground" material is intrusive to both the listener and to anyone else in the immediate area. No matter what "foreground" material is chosen, the fact remains that this material can be heard by anyone within its range and presents a definite distraction to other activities such as conversation, thought, desire to listen to other programming such as radio or television, need to concentrate, etc. Additionally, and because the tapes are used repeatedly by the same listener, any "foreground" music or material eventually becomes monotonously tiring to that listener.

It is the purpose of the following described invention to eliminate or greatly reduce all of the above deficiencies. Although its application to the magnetic tape medium is described in the following discussion, the technique is equally applicable to most other desired transmission mediums, such as Compact Disc, videocassettes, digital tape recorders, Public Address (PA) systems, background music installations, computer software programs, random access memory (RAM), read only memory (ROM), "live", real time applications and other mediums now in existence or to be developed in the future.

Implemented on tape cassettes, for example, the subliminal presentation described here is inaudible i.e., high audio or ultrasonic frequencies, the affirmations are presented at a constant, high amplitude level, and they occupy their own "clear channel", non-masked frequency allocations. If desired, the previously described "foreground" music or other material can be added to the tape through use of an audio mixer. The "silent" recordings are inaudible to the user or by others present and are therefore very effective for use during periods of sleep or when in the presence of others. Additionally, the basic requirements of subliminal stimulation are met. That is, the affirmations are efficiently transmitted to the ear and, while undetected by the conscious mind, are perceived by and efficiently decoded by the subconscious mind.

OBJECTS OF THE INVENTION

Accordingly, several objects and advantages of my invention are:

(a) to provide a technique for producing a subliminal presentation which is inaudible to the listeners(s), yet is perceived and demodulated (decoded) by the ear for use by the subconscious mind.

(b) to provide a technique for transmitting inaudible subliminal information to the listener(s) at a constant, high level of signal strength and on a clear band of frequencies.

(c) to provide a technique for producing inaudible subliminal presentations to which music or other "foreground" programming may be added, if desired.

Still further objects and advantages will become apparent from a consideration of the ensuing description and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings, the first digit of each component number also refers to the figure number where that component can be located.

FIG. 1 represents the block diagram of a suitable system which will generate a frequency modulated (FM) signal at 14,500 Hz.

FIG. 2 represents an approximation of the frequency response curve of the human ear and the signal decoding process.

FIG. 3 represents the block diagram of a suitable system which will generate a single sideband, suppressed carrier, amplitude modulated (AM) signal at 14,500 Hz.

38 bandpass filter	39 output signal

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Please refer now to FIG. **1** and FIG. **2**, which are drawings of a preferred implementation of the invention.

The principle of operation of the silent subliminal presentation system is as follows:

An audio signal in the upper frequency region of the audio spectrum (for example, 14,500 Hz) is modulated with the desired information. The type of modulation may be any type suitable for subliminal applications; frequency modulation (FM), phase modulation (PM), upper single sideband with suppressed carrier, amplitude modulation (AM), tone modulation, etc.

For broadest application, the high audio frequency selected as the carrier frequency must meet two basic criteria:

(1) be high enough in the audio spectrum that its presence to the human ear is essentially unnoticed or undetectable (without the listener being informed that the signal is actually present) and,

(2) be low enough in the audio spectrum that it (and its modulation content) can produce a useful output power from home entertainment type cassette or reel-to-reel magnetic recorders.

This would also include, of course, small portable and automobile tape decks.

Alternatively, the output of the system can be fed directly into an audio amplifier and its speaker/earphone system, Public Address system, etc.

FIG. **1** provides the block diagram of an example of a system capable of generating the desired silent frequency modulated carrier.

The modulation information is inputted into the microphone **11**. Other suitable input devices may be substituted for microphone **11**, such as a tape recorder or a radio. The microphone **11** is connected to the preamplifier **12** and should have provisions for adjusting its gain in order that the optimum modulation index can be set in the frequency modulator **13**. The frequency modulator **13** modulates the frequency of oscillator **14** which has been adjusted for an output of 14,500 Hz as described above. The output of oscillator **14** is fed through a suitable bandpass filter **15** into the tape recorder or directly into a suitable amplifier/speaker system. It is the purpose of the bandpass filter to remove or attenuate audible products of the modulation process in order to maintain as audibly silent an output as practical.

On the receiving end, FIG. **2** represents an approximate and idealized frequency response curve of the human ear. The frequency modulated carrier (centered at 14,500 Hz), as generated above and played through a tape recorder or amplifier/speaker system, is shown on FIG. **2** as speaker output **26**, impinging upon the upper slope of the ear's response curve at point **25**. The frequency modulated excursions of the speaker output **26** swing between points **23** and **24** on the ear's upper response curve. Because the response curve between points **23** and **25** is relatively linear, this action results in a relatively linear demodulation of the original modulation intelligence, which is passed on subliminally to the inner ear. The amplitude of the demodulated output is not high enough to be detected by the conscious mind but is sufficient in amplitude to be detected by the subconscious mind. In the field of communications engineering design, the above demodulation process in known as slope detection and was used in early FM receiver design. In those receivers, the response curve was formed by the action of a tuned (inductive/capacitance) circuit. In our case, the response curve is formed by the natural response curve of the human ear. The same slope detection technique can be performed at the low frequency end of the human ear response curve. This region is indicated on FIG. **2** as between points **21** and **22**. This region, however, has a much smaller available bandwidth and is therefore more restricted as to the amount of information that can be transmitted in an inaudible manner.

In practice, the listener adjusts the volume control of the tape recorder or amplifier to a level just below that at which the listener hears an audible sound or noise from the speaker of the tape recorder. If the recording process is properly done, a spectrum analyzer or a calibrated sound level meter will reveal a strong signal emanating from the tape recorder speaker. A calibrated sound level meter, at a distance of 1 meter (with C weighting and referenced to the standard of 0.0002 micro bar) will typically indicate a silent power output of from 60 to 70 decibels. This is equivalent to the audio power of a loud conversation, yet, in the described system, is inaudible or unnoticed by the listener.

FIG. **3** illustrates a system which generates a suitable amplitude modulated (AM) signal, instead of the frequency modulated (FM) system described above. The output is a modulated, single sideband (SSB), suppressed carrier (AM) signal at 14,500 Hz.

The block diagram represents a common scheme for generating an SSB signal and will be briefly described.

The desired subliminal information is spoken into microphone **31**. This signal is amplified by speech amplifier **32** and injected into one port of balanced modulator **33**. A continuous wave signal of **455** KHz is generated by carrier oscillator **34** and is injected into the second port of balanced modulator **33**. The output of balanced modulator **33** is a double sideband, suppressed carrier signal at 455 KHz. This signal is fed through filter **35**, causing one of the two sidebands to be removed. This signal is fed into one port of mixer **36**. A continuous wave signal at a frequency of 469.5 KHz from hetrodyne oscillator **37** is fed into the other port of mixer **36**, resulting in an output of the original subliminal audio information but translated 14,500 Hz higher in frequency. The bandpass filter **38** attenuates signals and noise outside of the frequencies of interest. The ampli-

tude modulated audio output signal is shown as output **39**.

Thus, as stated earlier, my invention provides a new system for subliminal presentations which is:

(a) silent,

(b) outputs a constant, high level modulated signal and,

(c) occupies a band of clear channel frequencies.

The foregoing description of the preferred embodiment of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above discussions. It is intended that the scope of the invention be limited not only by this detailed description, but rather by the claims appended hereto.

What is claimed:

1. A silent communications system, comprising:

(a) amplitude modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum said signals modulated with information to be perceived by a listener's brain and,

(b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain, of the listener, and,

(c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

2. A silent communications system, comprising:

(a) frequency modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum, said signals modulated with information to be perceived by a listener's brain, and;

(b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain of the listener, and;

(c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

3. A silent communications system, comprising:

(a) a combination of amplitude and frequency modulated carrier means for generating signals located in non-aural portions of the audio and in the lower portion of the ultrasonic frequency spectrum, said signals modulated with information to be perceived by a listener's brain, and

(b) acoustic and ultrasonic transducer means for propagating said signals, for inducement into the brain of the listener;

(c) recording means for storing said modulated signals on mechanical, magnetic and optical media for delayed or repeated transmissions to the listener.

[57] **ABSTRACT**

Improved methods and apparatus for entraining human brain patterns, employing frequency following response (FFR) techniques, facilitate attainment of desired states of consciousness. In one embodiment, a plurality of electroencephalogram (EEG) waveforms, characteristic of a given state of consciousness, are combined to yield an EEG waveform to which subjects may be susceptible more readily. In another embodiment, sleep patterns are reproduced based on observed brain patterns during portions of a sleep cycle; entrainment principles are applied to induce sleep. In yet another embodiment, entrainment principles are applied in the work environment, to induce and maintain a desired level of consciousness. A portable device also is described.

METHOD OF AND APPARATUS FOR INDUCING DESIRED STATES OF CONSCIOUSNESS

CROSS-REFERENCE TO RELATED APPLICATION

The present application is related to copending application No. 07/514,460, filed Apr. 16, 1990 now U.S. Pat. No. 5,213,562.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an improved method of inducing desired states of consciousness, including different levels of sleep, in human beings, using a technique known as frequency following response (FFR), developed by the present inventor. The invention also relates to apparatus for performing the method. A number of areas of applicability of the invention are described, in accordance with different preferred embodiments.

2. Description of the Background Art

In a prior patent, U.S. Pat. No. 3,884,218, the present inventor described a method of inducing different levels of sleep, using the FFR technique, in which brain waves could be made to follow superimposed frequency patterns. These frequency patterns were provided as sine waves, at frequencies known to correspond to different levels of sleep, such as alpha (exhibiting brain wave activity in the range of 8–12 Hz), theta (6–8 Hz), and delta (1–4 Hz). EEGs exhibiting frequencies between 12 and 30 Hz (known as a beta range) are characteristic of awake individuals, though beta activity at even higher frequencies has been observed in different types of mental activities. Gamma activity has been characterized as all activity above 30 Hz; until recently, it has not been possible to monitor brain activity in the gamma range. (It should be noted that the boundaries between gamma and beta, beta and alpha, alpha and theta, and theta and delta are somewhat arbitrary; the foregoing delineations are intended to be exemplary and not limiting.)

The present inventor discovered that the human brain could be entrained to output brain wave patterns these different frequencies. While frequencies corresponding to these different levels of sleep are not audible, by superimposing those frequencies on some type of sound, such as music, it was determined to be possible to induce desired levels of sleep. The individual listening to the music would "hear" the low frequencies, with the desired effect on brain activity.

An improvement on the inventor's patented technique, to induce varied states of alertness, is the subject of copending Application No. 07/514,460, the contents of which are hereby incorporated herein by reference. This copending application describes a general FFR technique using what is known as a binaural beat phenomenon, details of which are provided in that application. Briefly, a binaural beat is produced by sending signals at different frequencies (some Hz apart, depending on the desired effect) to an individual's left and right ears. The difference between the frequencies defines the frequency of the binaural beat. Using this technique, the desired frequency can be introduced into the individual's brain activity, inducing the desired state of consciousness.

The induction of FFR in the human brain in this manner results in the synchronization of activity in the hemispheres of the brain. FIG. 1A shows brain activity without FFR, and FIG. 1B shows brain activity with FFR. The inventor has coined the term HEMI-SYNC (for Hemisphere Synchronization) to describe this phenomenon.

The copending application describes a technique wherein, in one form, sine waves having a frequency corresponding to a consciousness state are superimposed on two different carrier frequencies to form two different signals to set up the binaural beat. In another form, an actual brain pattern, based on an electroencephalogram (EEG) waveform indicative of that consciousness state is superimposed on the different carrier frequencies to form two different signals. In use, each signal is provided to one ear of a subject. The difference in carrier frequencies sets up the binaural beat.

Another, more limited application of the binaural beat phenomenon is found in U.S. Pat. No. 4,834,701. In contrast to the narrow range of frequencies discussed in that patent, in the above-mentioned copending application, the applicability of the binaural beat phenomenon is investigated over a much wider range of frequencies, spanning the spectrum of brain activity.

Through additional investigation involving mapping of brain activities of different individuals, the present inventor has discovered some significance to the fact that, while brain waves at certain frequencies are characteristic of different levels of sleep, brain patterns of different individuals still vary. The inventor has investigated possible enhancements to the FFR effect by making it more generic among individuals, yet still more specific to brain activity than a simple sine wave, or an EEG of a particular individual.

Another area of investigation being performed by the present inventor relates to human sleep patterns. Based on current knowledge of human sleep patterns, it appears that sleep is composed of a series of 90-minute cycles. As stated earlier, the beta stage is one of alertness. The first sleep state is alpha, or mental and physical relaxation. The second is theta, or light sleep. Next is delta, or deep sleep. The inventor has investigated the possibility of providing FFR waveforms in cyclic patterns, replicating these human sleep patterns, to facilitate sleep. Another possibility is to take advantage of the cyclic nature of sleep patterns to provide a more gentle wake-up for a sleeper.

In considering the need for alertness during activities such as work, the inventor also considered how it might be possible to introduce FFR waveforms into ambient noise in one's surroundings to facilitate maintenance of desired states of consciousness. Particularly in environments such as factories, or in offices where office equipment puts out consistent types of noise, it would be desirable to be able to introduce a binaural beat into that noise at different frequencies, to enhance the degree of alertness of factory or office workers as desired.

SUMMARY OF THE INVENTION

In view of the foregoing, according to one aspect of the invention, EEGs for a number of individuals in different states of consciousness are sampled, and EEG waveforms for the group of individuals, corresponding to each identifiable state of consciousness, are combined. A binaural beat then is generated using the combined EEGs.

According to this aspect of the invention, it has been determined that using groups of EEG waveforms from different individuals and combining them to obtain a representative waveform yields a waveform that a person's brain is more likely to replicate than an individual EEG waveform, or a sine wave representation of the EEG waveform. The combination may be simple averaging, though other combination techniques, such as weighted averaging, for combining different numbers of EEG waveforms as desired, are contemplated. Now that the inventor has discovered that combinations of EEG waveforms provide a particularly effective entrainment environment, it will be seen that various ways of combining these waveforms may yield greater or lesser effects.

In accordance with another aspect of the invention, a method for replicating cyclic sleep patterns for a desired sleep period is provided. In a preferred embodiment according to this aspect of the invention, a subject is led from beta, to alpha, to theta, to delta, then back to theta, then alpha, then a rapid-eye movement (REM) or light dreaming sleep, in a sequence of 90-minute cycles, during a sleep period of desired duration. After the expiration of the period, the subject may wake up voluntarily. Alternatively, the invention can provide a gentle external stimulus to lead the subject to a beta state.

With respect to this aspect of the invention, an apparatus is provided which automatically leads an individual through these cyclic sleep patterns, and enables the individual to set a desired sleep period. This device preferably takes advantage of the techniques to be described relative to the first-mentioned aspect of the invention, but is not so limited. The inventive contributions of this second aspect of the invention are considered to lie in the combination of hardware itself which generates the desired sequence of binaural beats, as opposed to the particular software which determines the nature of those binaural beats. In one form, the invention is constituted by an alarm clock which provides a fade-in theta-alpha signal followed by a strong beta-gamma signal shortly before a desired wake-up time.

According to yet another embodiment of the invention, selectable mind-affecting sound patterns are provided to supplement constant ambient noise in any environment. When the noise is not present, the patterns are not provided. The patterns vary in amplitude in accordance with changes in the environmental noise.

In accordance with still another embodiment of the invention, a portable system is provided to enable the wearer to introduce binaural beat signals of frequencies that are selectable in accordance with a desired level of awareness. Depending on the level of sophistication of the device, the binaural beat may be generated using the combined EEG waveforms of the first aspect of the invention, but this last aspect of the invention is not so limited.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other aspects of the invention will be understood by those of working skill in this technological field by reference to the following detailed description of the preferred embodiments of the invention, read in conjunction with the accompanying drawings, wherein:

FIGS. **1A–1C** and **1D–1F** taken from the above-mentioned copending application, show one example of the results which can be achieved using the inventive techniques;

FIG. 2 is a block diagram of the hardware according to a second embodiment of the invention, and FIGS. **3–5** are more detailed schematics therefor;

FIGS. **6A–6J** are drawings, similar to FIGS. **1A** and **1B**, but showing brain activity during various stages of a sleep cycle, using a technique in accordance with the second embodiment of the invention;

FIG. 7 is a block diagram of hardware in accordance with a third embodiment of the invention;

FIG. **8A** is a block diagram of hardware in accordance with a fourth embodiment of the invention, and FIG. **8B** a schematic of that hardware; and

FIGS. **9A–9M** are graphs of different possible effects of the embodiment of FIGS. **8A** and **8B**, showing a baseline brain pattern, selected stimulus frequencies and corresponding stimulus waves, and associated response waves.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The method according to a first preferred embodiment of the invention, which has been developed through extensive experimentation, derives from the empirically-observed phenomenon that brain patterns of human subjects are entrained more readily to brain patterns which more closely match their own. In prior implementations of the FFR technique, such as in the inventor's prior patent, in which sine waves having frequencies corresponding to desired levels of sleep were superimposed upon a given frequency, entrainment did occur. Use of the binaural beat phenomenon yielded better results, through synchronization of the hemispheres of the brain.

However, simple repetitive frequencies, or even combinations of such frequencies within different ranges, do not represent brain patterns per se, but rather provide entrainment environments for the brain to follow. It has been determined that, the more closely the entrainment environment parallels normal brain function at different levels of consciousness, the more effective the entrainment effect. This phenomenon is what led to the improvement disclosed in the above-mentioned copending application.

As a further improvement on that technique, as mentioned above, the present inventor investigated the possibility of creating more generic models of brain function at different levels of consciousness. As a result of that investigation, it was determined that combinations of EEG waveforms from different individuals functioning at the same identifiable level of consciousness (e.g. alpha sleep, theta sleep, or delta sleep) provided a superior entrainment environment. In the inventive method according to this aspect of the invention, the brain patterns of 40 to 50 individuals were combined to yield the entrainment environment.

One area of applicability of the techniques of the present invention is in the area of sleep therapy. Many individuals suffer from sleep disorders to varying degrees. It is possible to provide a suitable entrainment environment, based on known sleep cycles prevalent in humans, to help individuals to regulate their sleep patterns, and thus help to solve their sleep disorders. One embodiment of the invention, shown in FIG. 2 and also in FIGS. 3–5, implements the inventive techniques in what the inventor calls a Sleep Processor to aid in the regulation of human sleep cycles.

In FIG. 2, a read-only memory (ROM) 10 stores frequency sequences corresponding to different parts of a human sleep cycle. The stored frequency sequences may be in accordance with a predetermined algorithm, or alternatively may provide a less complex entrainment environment, such as simple averaging. A digital signal processor (DSP) **20** selects different ones of these sequences based on the current time and the time to which an alarm is set. The time is displayed on display **30**, and is set using time set **40**. The alarm is set to a desired wake-up time using alarm set **50**.

During operation, the DSP **20** accesses the ROM **10** and provides an output to a pulse code modulator unit (PCM) **60** accordingly. The PCM **60** provides an output to each of left and right channel speakers **70, 80** which are provided in close proximity to the ears of a human subject. Using headphones enhances the effect.

Some additional detail of operation of the DSP **20** in one aspect of this embodiment now will be provided. A serial port in the DSP **20** generates an interrupt at a 50 KHz rate. An interrupt handler in the DSP **20** computes the various sounds, in one form, by generating sine waves using a pair of integrators:

$\text{cosine} = \text{cosine} + \text{frequency} \times \text{sine}$

$\text{sine} = \text{sine} - \text{frequency} \times \text{cosine}$

The Sleep Processors needs ten frequencies, five for each channel, and all of these frequencies are generated at the same time. The results are multiplied by ten envelopes, most of which are zero at any moment.

Noise is generated by a well-known 16-bit shift-register algorithm. This algorithm generates a noise signal that repeats every 65535 samples, or about every five seconds. The noise is filtered to sound more like pink or red noise, and less like white noise, and is written into a delay line in RAM. For each channel, the filtered noise is averaged with an earlier sample from the delay line, thus imparting a comb filter response to it.

An additional low-frequency sine/cosine pair is generated, to sweep the comb filter delay. 32-bit arithmetic is used here. The approximate sweep rate is about 1/8 Hz. The low-frequency sine wave is used directly to sweep the delay on one channel. The delay on the other channel is controlled by some mix of the sine and cosine waves. By choosing these and other coefficients properly, any phase and amplitude relationship between the left and right sweep can be obtained. The comb filtered noise for each channel is multiplied by a noise envelope value.

The device is operated as follows. A desired wake-up time is set, much like an alarm clock, and the desired volume is selected. A start/stop button then is pressed to start the cycles for the selected sleep period. Throughout the sleep period, the device repeats a 90 minute cycle of sound that leads the subject through alpha, theta, delta, and back to dreaming sleep. Five minutes before the scheduled wake-up time, a beta signal is introduced to bring the subject back to complete physical wakefulness. When the subject wakes up, he/she hits the start/stop button again to stop the sound sequence.

The sounds produced by the DSP **20** include binaural beat carrier sound patterns utilizing both amplitude and frequency modulation, masking pink sound (a known type of sound described in the copending application), and, optionally, occasional single-word voiced affirmations. The binaural beat audio signals may be in the form of appropriate sine waves, or alternatively may be replicas of actual EEG brain waveforms. In the latter case, either the just-described combined EEG waveforms or a single EEG waveform (as described in the copending application) may be used. The entire pattern of sound and control is generated algorithmically.

One aspect of the effectiveness of the device of FIGS. 2–5 is the spacing of sound carriers at related frequencies so as to engender binaural beat signals not only from channel to channel, but also monaurally, in each audio channel. In this preferred embodiment, three binaural beat frequency signals are created between audio carrier channels, and two amplitude beats per channel also are created, yielding a total of seven beat signals. The inventor has coined the term Septon for this set of beat signals. One example of a septon is as follows:

Left Channel		Right Channel
200 Hz carrier (4 Hz monaural beat)	(4 Hz binaural beat)	204 Hz carrier (4 Hz monaural beat)
204 Hz carrier (4 Hz monaural beat)	(4 Hz binaural beat)	208 Hz carrier (4 Hz monaural beat)
208 Hz carrier	(4 Hz binaural beat)	212 Hz carrier

A standard program according to this preferred embodiment would employ the following sound sequence:

0–5 minutes:
Signal Group A (comprised of replicated EEG waveforms having dominant values in the alpha range)
Signal Group B (15 dB below Group A, generated simultaneously with the sounds of Group A, and comprised of replicated EEG waveforms having dominant values in the theta range)
Phased Pink Sound (six seconds, peak-to-peak, on both left and right channels, 20 dB below Group A)
Voice Inserts (repeated at 40 second intervals, 10 dB below Group A, simultaneously with the other sounds, and comprising short sequences of phrases like "relax" "let go", and "sleep")
5–20 minutes:
Signal Group B
Signal Group C (20 dB below Group B, generated simultaneously with Group B, and comprised of replicated EEG waveforms having dominant values in the delta range)
Phased Pink Sound (15 dB below Group B, having a duration as in the first interval)
Voice Inserts (10 dB below Group B, comprised as above)
20–40 minutes:
Signal Group C
Signal Group D (10 dB below Group C, generated simultaneously with Group C, and comprised of replicated EEG waveforms having dominant values in the lower delta range)
Phased Pink Sound (10 dB below Group C, having a duration as in the first interval)
Voice Inserts (20 dB below Group C, comprised as above) 40–65 minutes:
Signal Group D
Phased Pink Sound (10 dB below Group D, having a duration as in the first interval)
Voice Inserts (20 dB below Group D, comprised as above) 65–80 minutes:
Signal Group C
Signal Group D (10 dB below Group C, generated simultaneously with Group C)
Phased Pink Sound (15 dB below Group C, having a duration as in the first interval)

NO voice inserts

80–90 minutes:

Signal Group B

Signal Group C (10 dB below B, generated simultaneously with Group B)

Phased Pink Sound (15 dB below Group B, having a duration as in the first interval)

NO voice inserts

The foregoing sequence is repeated through the sleep period until the wakeup sequence, approximately five minutes before the set wake-up time:

Signal Group AA (a wakeup sequence, comprising replicated EEG waveforms having dominant values in the beta range, or alternatively a 400 Hz/416 Hz envelope yielding frequencies in the beta range)

Voice inserts (10 dB below Group AA, comprised of short phrases such as "waking up", "refreshed", "bright", and repeated at intervals)

One variation of the foregoing embodiment is an alarm clock which, instead of sounding a loud alarm or other jarring noise at wake-up time, starts a gentle sequence of signals some minutes before, to bring an individual up gently through the various levels of sleep to full wakefulness. A fade-in theta-alpha signal may be provided, followed by a stronger beta-gamma signal.

FIGS. **6A** to **6J** show the effects of the just-described "sleep processor" embodiment. Column **1** shows distribution of delta frequencies; column **2** shows distribution of theta frequencies; and column **3** shows distribution of alpha frequencies. The top row of graphs is the actual pattern observed in the individual, and the bottom row is the baseline pattern.

FIG. **6A** corresponds to a normal waking state. Dominant alpha activity is shown in the occipital area of the brain. In FIG. **6B**, pink noise has been applied, without any beat frequencies. A narrower focus of waking state is shown.

In FIG. **6C**, a signal sequence corresponding to Signal Group A has been applied. Some gain in theta frequencies are seen, with rapid diffusion of alpha frequencies and movement toward the vertex of the head. In FIG. **6D**, a signal sequence corresponding to Signal Group B has been applied. There is further diffusion of alpha frequencies, with some movement of delta and theta activity toward the pre-frontal cortex of the brain.

In FIG. **6E**, a signal sequence corresponding to Signal Group C has been applied. There is rapid diffusion of alpha frequencies, and increased power of theta and delta frequencies. In FIG. **6F**, a signal sequence corresponding to Signal Group D has been applied. Alpha frequencies are diffused further toward the pre-frontal cortex, and there is a marked increase in theta and delta frequencies.

FIG. **6G**, continuing application of Signal Group D frequencies, shows a marked increase in delta activity in the pre-frontal cortex, with a steady decrease in alpha activity at the vertex. In FIG. **6H**, another binaural beat stimulation has been applied, and characteristics of stage **3** and **4** sleep may be observed. In FIG. **6I**, further evidence of the further binaural beat stimulation is observed. Delta is the dominant frequency here. Alpha and theta activity has moved to the prefrontal cortex. Finally, FIG. **6J** shows early awakening activity, with a diffusion of delta activity.

FIG. **7** is a block diagram of hardware in accordance with another embodiment of the invention, having application to the work environment, or anywhere a constant source of noise is present, to allow workers, for example, to maintain a desired state of awareness. The device may contain suitable digital signal processor circuitry, as in the preceding embodiment. One difference is that the operation of the device is keyed to the presence of ambient noise, not to a given time duration or selected sleep period.

The device of FIG. **7** includes a sound generator **200** which, as just mentioned, may comprise a digital signal processor. The generator **200** outputs sound patterns via one or more speakers (left and right channel speakers **210, 220** are shown). A sound level detector **230** detects the level of ambient noise in the room, and provides a signal to the sound generator **200**, or activates a cut-off switch (not shown), to discontinue output of the sound generator **200** when the ambient noise level drops below a predetermined level.

The sound level detector also preferably provides a signal to the sound generator **200** to boost the sound pattern output when the ambient noise level increases, so that the effect of the provision of the sound pattern is commensurate with the noise level in the room. Alternatively, the user may simply adjust the volume manually, using one or more knobs (not shown) on the sound generator **200**.

A timer **240** may be provided to control the duration of provision of the selected sound pattern, or even to change the sound pattern at different times of day by controlling a selector **250** which the user accesses to select a particular sound pattern to be output. The user may select a given sound pattern in the morning, and the timer **240** may change that pattern automatically, based on a need at different times of day for sound patterns providing different states of alertness.

The sound pattern produced by the device of FIG. **7** varies automatically in amplitude in accordance with changes in the ambient noise, and is discontinued when the noise stops. As a result, the sound remains unobtrusive. Depending on the setting, the produced sound pattern can enhance wakefulness, promote relaxation (as, for example, in rest areas in the workplace), reduce anxiety and stress, or focus attention, among other characteristics.

The basic system of FIG. **7** produces and inserts four different sound patterns which are selected manually so as to merge the output into the constant ambient noise. More sound patterns are possible, depending on the desired overall capabilities of the system. Various modifications are possible. For example, a programmable version may be provided, which changes the form of the sound patterns throughout a work day or night, in accordance with the responses desired.

Selectability of patterns may be accomplished differently in a model intended for use in conjunction with a computer system. The computer operator can input a selection, and may vary that selection as desired throughout the work day.

FIG. **8A** is a diagram of a portable embodiment of the invention, for use in providing a desired level of consciousness on an individualized basis. A signal generator **300** preferably includes a digital signal processor **310** and a ROM **320** for storing predetermined signals or sequences of signals which correspond to various desired states of awareness. The signal generator **300** may be a simple tone generator or pair of tone generators which provide outputs to speakers or headphones **330** (such as button-sized headphones) to set up a binaural beat. Output of pink sound or phased pink sound by the generator **300** is desirable to facilitate defocusing of the listener and consequent ability to concentrate on the sounds being produced. A selector **340** enables a user to instruct the signal generator **300** to output signals corresponding to the level of consciousness (e.g. focused concentration, relaxation, alertness) that a user desires.

FIG. **8B** shows a schematic of this embodiment, which the inventor calls a "Mood Minder". This embodiment includes a selector for selecting one of four possible types of signals, corresponding to four respective levels of awareness: awake and alert; concentration; attention; and relaxation. However, the invention is not so limited, as the generator **300** may be capable of producing other possible types of signals. Alternatively, pre-set patterns in the generator **300** may vary when specialized use is required. The key to this embodiment is its portability, enabling the user to carry the device everywhere. The device is battery-operated, and is small enough to fit in an upper coat pocket, for example.

FIGS. **9A–9M** show examples of prestored patterns produced by the generator **300**, and of results achieved in use. FIG. **9A** shows baseline brain waves, with relative power output shown at the right for different frequencies. FIGS. **9B**, **9E**, **9H**, and **9K** show the stimulus frequencies produced for four different respective states of consciousness. FIGS. **9C**, **9F**, **9I**, and **9L** show the stimulus waves corresponding to the superposition of the stimulus frequencies on the baseline wave. FIGS. **9D**, **9G**, **9J**, and **9M** show the results achieved in use. As can be seen, the peak-to-peak amplitudes for the response brain waves correspond closely to those of the stimulus waves.

While the present invention has been described in detail with reference to preferred embodiments, various modifications within the scope and spirit of the invention will be apparent to those of working skill in this technological field. Consequently, the invention should be considered as limited only by the scope of the appended claims.

What is claimed is:

1. A method of inducing desired states of consciousness in human beings, comprising the following steps:

combining a plurality of replicated electroencephalogram (EEG) waveforms, each indicative of a particular desired state of consciousness, to produce a combined EEG waveform;

superimposing said combined EEG waveform on two separate sets of carrier waves using stereo sound;

creating differential beat frequencies between said sets of carrier waves based on said superimposing step; and

providing the resulting signals in audio form to respective ears of a human being, to induce said state of consciousness.

2. A method as claimed in claim **1**, wherein said combining step comprises mathematically averaging said EEG waveforms to produce said combined EEG waveform.

3. A method as claimed in claim **1**, further comprising the step of repeating said combining, superimposing, and creating steps for each of a set of desired states of consciousness, and producing a cycle of sets of resulting audio signals, said providing step comprising providing said cycle of sets of resulting audio signals to respective ears of a human being, to induce each of said desired states of consciousness in cyclic fashion.

4. A method as claimed in claim **3**, wherein said cycle corresponds to human sleep patterns, said desired states of consciousness comprising wakefulness, alpha sleep, delta sleep, and theta sleep.

5. A method as claimed in claim **3**, wherein said cycle corresponds to human sleep patterns, said desired states of consciousness comprising alpha sleep, delta sleep, and theta sleep, said cycle being approximately 90 minutes long.

6. A method as claimed in claim **5**, said method further comprising the steps of providing a plurality of repetitions of said cycle, followed by providing a set of audio signals containing a binaural beat at a frequency indicative of beta consciousness.

7. A method as claimed in claim **1**, wherein said creating step includes the step of combining pink sound with said sets of carder waves by shifting of said pink sound with respect to said combined EEG waveform from one stereo audio channel to another, with cyclic changes in amplitude, frequency, and rate of panning.

8. Apparatus for facilitating sleep in a human subject, comprising:

means for setting a wake-up time to select a desired sleep duration;

means for generating a first sequence of signals in a cycle corresponding to a human sleep pattern, frequencies of said signals in said first sequence being substantially equal to frequencies of human brain patterns at different levels of sleep;

means for repeating said cycle a plurality of times based on the selected wake-up time; and

means for waking up said human subject at the selected wake-up time.

9. Apparatus as claimed in claim **8**, wherein said means for waking up said human subject comprises means for generating a second sequence of signals a predetermined time before the selected wake-up time, frequencies of said signals in said second sequence being substantially equal to frequencies of human brain patterns at or near an awakened state.

10. Apparatus as claimed in claim **9**, wherein said predetermined time is approximately five minutes.

11. Apparatus as claimed in claim **8**, wherein said first sequence of frequencies comprises, in order, alpha frequencies, theta frequencies, delta frequencies, and theta frequencies.

12. Apparatus as claimed in claim **8**, further comprising means for generating phased pink sound in conjunction with said first sequence of frequencies.

13. Apparatus as claimed in claim **8**, wherein said first sequence of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of sleep, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective level of sleep.

14. Apparatus as claimed in claim **13**, wherein said EEG waveforms are mathematically averaged.

15. Apparatus for awakening an individual using brain pattern entrainment, said apparatus comprising:

means for selecting a wake-up time;

means for keeping time; and

means, operative a predetermined period before said wake-up time as determined by said means for keeping time, for producing a first sequence of signals having frequencies in the theta-alpha range, followed by a second sequence of signals having frequencies in the beta-gamma range.

16. Apparatus as claimed in claim 15, wherein said means for producing said first and second sequences of signals comprises means for producing said second sequence of signals at a higher amplitude than said first sequence of signals.

17. Apparatus as claimed in claim 15, wherein said first sequence of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of consciousness, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective level of consciousness.

18. Apparatus as claimed in claim 16, wherein said EEG waveforms are mathematically averaged.

19. Apparatus for inducing a desired state of consciousness, said apparatus comprising:

means for detecting presence of a predetermined level of ambient noise;

means, responsive to said detecting means, for generating signals having frequencies substantially equal to frequencies of human brain patterns when said ambient noise is present; and

means for selecting said signals in accordance with desired human activity in said areas.

20. Apparatus as claimed in claim 19, further comprising timer means, connected to said generating means, for generating said signals for a predetermined time set by said timer means.

21. Apparatus as claimed in claim 19, wherein said timer means is connected to said selecting means to enable selection of different ones of said signals in accordance with desired human activity at different times of day.

22. Apparatus as claimed in claim 19, wherein said generating means comprises means, responsive to said detecting means, for increasing an amplitude of said signals in response to an increase in amplitude of said ambient noise, and for decreasing an amplitude of said signals in response to a decrease in amplitude of said ambient noise.

23. Apparatus as claimed in claim 22, wherein said generating means further comprises means for discontinuing said signals when said ambient noise falls below said predetermined level.

24. Apparatus as claimed in claim 19, wherein said generating means comprises a digital signal processor and a read-only memory (ROM) connected to said digital signal processor, said ROM storing a plurality of sets of signals, each of said sets of signals having frequencies substantially equal to human brain patterns at a desired state of consciousness.

25. Apparatus as claimed in claim 24, wherein each of said sets of signals comprises a plurality of sets of combined brainwaves, each of said sets corresponding to a different level of consciousness, said combined brainwaves within a given set being constituted by combined electroencephalogram (EEG) waveforms of a plurality of individuals, taken when said individuals had attained a different respective state of consciousness.

26. Apparatus as claimed in claim 25, wherein said EEG waveforms are mathematically averaged.

27. Apparatus for awakening an individual using brain pattern entrainment, said apparatus comprising:

means for selecting a wake-up time; and

means, operative a predetermined period before said wake-up time, for producing a first sequence of signals having frequencies in a first predetermined range corresponding to a first state of consciousness, followed by a second sequence of signals having frequencies in a second predetermined range corresponding to a second state of consciousness.

28. Apparatus as claimed in claim 27, wherein said first predetermined range is the theta-alpha range, and said second predetermined range is the beta-gamma range.

Primary Examiner—Bentsu Ro

[57] **ABSTRACT**

An energy conversion device includes a discharge tube which is operated in a pulsed abnormal glow discharge regime in a double ported circuit. A direct current source connected to an input port provides electrical energy to initiate emission pulses, and a current sink in the form of an electrical energy storage or utilization device connected to the output port captures at least a substantial proportion of energy released by collapse of the emission pulses.

ENERGY CONVERSION SYSTEM

REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. application Ser. No. 07/922,863, filed Jul. 31, 1992 (abandoned), and is also a continuation-in-part of U.S. patent application Ser. No. 07/961,531, filed Oct. 15, 1992, now U.S. Pat. No. 5,416,391.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to energy conversion circuits utilizing discharge tubes operating in the pulsed abnormal glow discharge (PAGD) regime.

2. Review of the Art

Such discharge tubes and circuits incorporating them are described in our copending U.S. patent application Ser. Nos. 07/922,863 and 07/961,531. The first of these applications discloses discharge tube constructions particularly suited for PAGD operation, and the second discloses certain practical applications of such tubes, particularly in electric motor control circuits. The review of the art contained in those applications is incorporated herein by reference, as is their disclosure and drawings.

It is known that there are anomalous cathode reaction forces associated with the cathodic emissions responsible for vacuum arc discharges, the origin and explanation of which have been the subject of extensive discussion in scientific literature, being related as it is to ongoing discussion of the relative merits of the laws of electrodynamics as variedly formulated by Ampere, Biot-Savart and Lorentz. Examples of literature on the subject are referenced later in this application.

SUMMARY OF THE INVENTION

The particular conditions which prevail in a discharge tube operated in the PAGD regime, in which a plasma eruption from the cathode is self-limiting and collapses before completion of a plasma channel to the anode gives rise to transient conditions which favour the exploitation of anomalous cathode reaction forces.

We have found that apparatus utilizing discharge tubes operated in a self-sustaining pulsed abnormal glow discharge regime, in a double ported circuit designed so that energy input to the tube utilized to initiate a glow discharge pulse is handled by an input circuit substantially separate from an output circuit receiving energy from the tube during collapse of a pulse, provides valuable energy conversion capabilities.

The invention extends to a method of energy conversion, comprising initiating plasma eruptions from the cathode of a discharge tube operating in a pulsed abnormal glow discharge regime utilizing electrical energy from a source in a first circuit connected to said discharge tube, and capturing electrical energy generated by the collapse of such eruptions in a second circuit connected to said discharge tube.

SHORT DESCRIPTION OF THE DRAWINGS

The invention is described further with reference to the accompanying drawings, in which:

FIG. 1 shows variation of applied DC current and pulse AC rms currents characteristic of a low current PAGD regime, as a function of decreasing pressure, for a 128 cm^2 H34 aluminum plate pulse generator having a 5.5 cm gap length and being operated in the single or plate diode configuration of FIG. 11A, at ~600 VDC.

FIG. 2 shows variation of applied DC current and AC rms currents of a high current PAGD regime, as a function of the decreasing pressure, for a device identical to that of FIG. 1, and operated at the same potential.

FIG. 3 shows PAGD rate vs. pulse generator cathode temperature as a function of the time of continuous PAGD operation, for a pulse generator with 64 cm^2 plates having a 4 cm gap distance, operated at VDC=555 (av) and R1=600 ohms (see FIG. 9).

FIG. 4 shows PAGD frequency variation with time, for 18 successive spaced one-minute PAGD runs for a pulse generator with 128 cm^2 plates, and a 5.5 cm gap distance, operated at VDC=560 (av) and R1=300 ohms.

FIG. 5 shows variation of the PAGD frequency in pulses per minute (PPM) with increasing charge of a PAGD recovery charge pack (see FIG. 9), as measured in terms of the open circuit voltage following 15 minutes of relaxation after each one minute long PAGD run, repeated 18 times in tandem, under similar conditions to FIG. 4.

FIG. 6 shows volt amplitude variation of continuous PAGD at low applied current, as a function of decreasing air pressure, for a 128 cm^2 plate area device, gap length=5 cm; (DCV at breakdown=860).

FIG. 7 shows volt amplitude variation of continuous PAGD at high applied current as a function of the decreasing air pressure, for a 128 cm^2 plate area device, gap length=5 cm; (DCV at breakdown=860).

FIG. 8 is a schematic diagram of a first experimental diode (without C6) or triode PAGD circuit.

FIG. 9 is a schematic diagram of a preferred diode or triode PAGD circuit in accordance with the invention.

FIGS. 10A, 10B and 10C are fragmentary schematic diagrams showing variations in the configuration of the circuit of FIG. 9.

FIG. 11 is a modification of FIG. 9, in which an electromagnetic machine, in the form of an electric motor, is connected into the circuit as an accessory electromechanical arm.

FIG. 12 shows a further development of the circuit of FIG. 9, permitting interchange of driver pack and charge pack functions.

FIG. 13 shows open circuit voltage relaxation curves for battery packs employed in tests of the invention, respectively after pre-PAGD resistive discharge (DPT1 and CPT1), after a PAGD run (DPT2 and CPT2) and after post-PAGD resistive discharge (DPT3 and CPT3).

FIG. 14 shows an example of negligible actual power measurements taken immediately before or after a PAGD run, showing both the drive pack loss and the charge pack gain in DC Watts; DP resistance=2083 ohms; CP resistance=833 ohms.

FIGS. 15A and 15B show resistive voltage discharge curves for two separate lead-zero gel-cell packs utilized respectively as the drive and the charge packs; load resistances employed were 2083 ohms across the drive pack (FIG. 15A) and 833 ohms across the charge pack (FIG. 15B).

FIG. 16 shows resistive discharge slopes for a drive pack before and after a very small expenditure of power in providing energy input to a PAGD run; R=2083 ohms.

FIG. 17 shows resistive discharge slopes for a charge pack before and after capturing energy from the collapse of PAGD pulses in the same test as FIG. **15**; $R=833$ ohms.

FIG. **18** shows resistive discharge slopes for a drive pack before and after a very small expenditure of power in providing energy input to a PAGD run in a further experiment; $R=2083$ ohms.

FIG. **19** shows resistive discharge slopes for a charge pack before and after capturing energy from the PAGD run of FIG. **18**; $R=833$ ohms.

FIG. **20** shows an example of operational measurements taken videographically during a 10 second period for both the power consumption of the drive pack (PAGD input) and the power production captured by the charge pack (PAGD output); the two values are also related by the expression of percent breakeven efficiency.

FIG. **21** shows variation of PAGD loaded voltage of a drive pack (in squares) compared with the PAGD charging voltage of the charge pack (in circles), during more than 1 hour of continuous PAGD operation.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The basic PAGD function and the construction of discharge tubes specifically designed for PAGD operation are described in our corresponding copending applications Nos. 07/922,863 (the '863 application) and 07/961,531 (the '531 application). For purposes of the experiments described below four aluminum H34 plate devices (one with 64 and three with 128 cm^2 plate areas) and three aluminum (H200) plate devices (one with 64 and two with 128 cm^2 plate areas), with interelectrode gap lengths of 3 to 5.5 cm, were utilized at the indicated vacua, under pumpdown conditions and with either air or argon (ultra high purity, spectroscopic grade 99.9996% pure) constituting the residual gas mixture. The pumpdown conditions were as described in the '863 application. Some experiments were performed with the tubes under active evacuation, at steady-state conditions, while others utilized sealed devices enclosing the desired residual gas pressures.

The circuit designs utilized in the various experiments to be described are set out further below, and represent further developments and extensions of the circuits set forth in the '531 application.

Test equipment utilized was as follows:

An Edwards (trade mark) thermocouple gauge (TC-7) was employed for the determination of pressure down to 1 micron of mercury (0.001 Torr).

Banks of Beckman (trade mark) rms multimeters 225 and 330 (30 and 100 kHz bandwidths, respectively) were utilized for all current measurements.

Frequency meters capable of discriminating events up to 0.1 nanosecond apart, and having adjustable amplitude windows, were used. Direct analysis on a Tektronix (trade mark) dual-trace, storage scope (Model 549) was also carried out for both parameters.

Split-phase, single-phase and two-phase motors were employed, of the synchronous, induction and universal types, as previously described in the '531 application, in the accessory electromechanical arm that may be coupled to the power producing circuit described in the present application.

Large banks of 12 V, 6 Ah lead-acid gel cells (Sonnenschein (trade mark) A212/6S) were utilized either as power sources (designated as drive packs) or as accumulators of the energy (referred to as charge packs) captured by the test circuits. Charge packs made of rechargeable 9 V NiCad or of nominally nonrechargeable C-Zn or alkaline batteries were also utilized.

PAGD emission areas were determined by metallographic examination of a series of craters produced by PAGDs in clean H34 cathodes, under a metallurgical Zeiss (trade mark) standard 18 microscope equipped with an epi-fluorescent condenser, very high power apochromatic objectives and a 100 W mercury lamp. For best results a focusable oblique source of light (12 V halogen) was also added to the incident light.

Following our low and high applied current studies on PAGD production as set forth in the '863 application, we noticed that the AC rms value of the component associated with each abnormal glow discharge pulse varied nonlinearly with the magnitude of the applied current. We originally noted the existence of a current induced shift of the entire PAGD region upward in the pressure scale: while the PAGD regime became more clearly defined as the applied constant DC was increased, the pressure required to observe the PAGD increased two to three orders of magnitude. In the course of these rarefaction studies we found that, at applied currents of 1 mA or less, the rms value of the different AC waveforms associated with the consecutive regimes of the discharge (TRD→NGD→AGD+PAGD) was, by more than half log, inferior to the value of the applied DC current, during the first two regimes (TRD and NGD) and reached a value equivalent to the applied current with the onset of spontaneous PAGD, at pressures <0.1 Torr (see FIG. **1**); however, in the downward tail of the PAGD regime (down to $3*10-3$ Torr), the AC rms current component of each PAGD again decreased to more than half log of the intensity of the applied DC value, in a manner proportional to the log of the decreasing pressure. In stark contrast, at high applied currents of ~500 mA, and aside from the high current-induced upward shift in pressure of the PAGD regime (to the point that the compression of the previous regimes on the pressure scale results in their suppressing, as was the case in the present example), the AC rms component associated with each pulse (see closed circles, FIG. **2**) is, from onset of the discharge at ~8 Torr, greater in magnitude than the value of the applied current (open circles, FIG. **2**). Under the conditions described, the distribution of the field current associated with each pulsed abnormal glow discharge approached (on a linear Y axis; not shown) an unimodal gaussian distribution with the pressure peak at ~1 Torr, and a corresponding observed maximum of 7.5× higher AC rms values than the applied DC values.

We have previously described in the '863 application how the PAGD frequency is affected by several factors, namely: the magnitude of the parallel discharge capacitance, the value of the negative pressure for the relevant vacuum PAGD range, the magnitude of the applied potential, the magnitude of the applied direct current, the interelectrode gap distance and the area of the parallel plate electrodes. In the '531 application we have also described how the wiring configuration (plate diode versus triode) affects the PAGD frequency by adding tungsten autoelectronic emissions from the axial electrode, to those emissions from the plate. There are other factors which limit the PAGD regime of discharge and have also been discussed in the '863 application. The following data indicates their specific effect upon PAGD frequency.

In the data presented in Table 1, control of the frequency parameter for the circuit shown in FIG. 9 is by a ballast resistance R1 within a specific range of interest (~800–150 ohms, for Table 1 experimental conditions), and this in turn increases the applied current which, at "high current" values (i.e. >100 mA, as for Table 1 conditions), will drive the PAGD frequency up, as previously reported in the '863 application.

Table 2 shows the effect of the progressive displacement of a given frequency, chosen as 200 PPS, with the cumulative pulse count of the same device, in the plate diode configuration. This displacement of the same frequency (cf. group #'s 1–3, Table 2) onto higher pressure regions is shown to be promoted by the alteration of the work function of the PAGD emitting cathode, such as this is caused by the cumulative pulse count and resultant crater formation on the electrode surface. After the first million pulses, the anode facing cathode surface is completely turned over by emission sites, and this corresponds well to the threshold crossed by group #2, Table 2. Once the cathode surfaces are broken in, the rates shown in groups #3 and 4, Table 2, tend to remain constant. Originally we wondered whether this might be caused by the alteration of the electrostatic profile of the plasma sheaths at the periphery of the envelope, due to the mirroring deposits that result from the sputter of ions and trapped neutral atoms (from air gases or metallic vapor) associated with the autoelectronic emission mechanism (and from further emissions triggered in turn, by secondary ionic bombardment of the cathode with molecular species present in the plasma ball formed over the primary emission site). However, reversal of the plate polarity (firing the ex-anode as a crater-free cathode) for over a million counts, followed by re-reversal to the original polarity, the entire operation being performed in air as the residual gas substrate, led to the partial recovery of the original work function for as long as the test was run ($1.5*10^4$ pulses), as shown by a comparison of groups #2,4 and 5, Table 2. From a metallographic examination of the surfaces of plates used solely as anodes, we have also concluded that prolonged PAGD operation has the effect, not only of cleaning the anode surface from surface films and adsorbed gases, as ionic bombardment promoted by electromagnetic induction coils does, but it also does more—it polishes the target surface and smooths it by a molecular erosive action. Observations of the surface of reversed cathodes, shows the same smoothing and polishing effects observed in exclusive anodes. Thus the recovery of the PAGD rates promoted by polarity reversal of the plates is not a function of the sputter-promoted mirroring deposits on the envelope wall, but a function of the actual work-function of the emitting cathode.

Another variable that interacts with the PAGD frequency is the molecular nature of the residual gas: Table 3 shows the differential frequency response of air with a halogen quencher, argon, for the same pulse generator employed in the tests of Table 2. It is apparent that argon obtains much higher rates of AGD pulsation for the same range of negative pressure, for the same "broken in" cathode, than does the air mixture. All these measurements were taken at cathode support-stem temperatures of 35° C.

Time of operation is also a variable affecting the frequency and operating characteristics of the cathode, as it becomes expressed by the passive heating of the cathode, an effect which is all the more pronounced at the higher pressures and at the higher frequencies examined. Utilizing the triode circuit discussed in the next section, the pulse rate of a PAGD generator with 64 cm^2 plates can be seen (see FIG. 3) to decrease, at a negative pressure of 0.8 Torr, from 41 PPS to the operating plateau of 6 PPS within 15 minutes of continuous operation, as the temperature of the cathode support increased from 19° to ~44° C. As the temperature plateaus at ~51°±1° C., so does the pulse rate at 6 PPS, for the remaining 48 minutes of continuous operation.

However, in order to confirm this time-dependent heating effect and threshold, we also performed the same experiment, utilizing the same circuit and the same negative air pressure, with twice as large a cathode area (128 cm^2, which should take nearly twice as long to heat), being operated for 18 one-minute long continuous periods equally spaced apart by 15 minutes of passive cooling, with the cathode stem always at 19.7° to 21° C., room temperature at the start of each period. The results surprised us, inasmuch as they showed that for a larger area tube which takes longer to heat to the same temperatures at comparable rates of PAGD triggering, one could observe a much earlier frequency reduction (by half, within the first 5 minutes or periods of interrupted functioning) in the absence of any significant heating effect (<1.5° C.) of the cathode (see FIG. 4). Repetition of these experiments has led us to conclude that, as shown in FIG. 5, the variable responsible for this repeatedly observed reduction in the PAGD frequency, when the PAGD operation sequence is systematically interrupted, is the state of charge/discharge of the battery pack (the charge pack) at the output of the triode circuit in question: the PPM rates in FIG. 5 decrease rapidly with the steepest rate of charging of the charge pack and the fastest recovery rate of its open circuit voltage; above a given state of charge, when the open voltage of the charge pack climbs more slowly (>340 V), in a log fashion, the PPM rate stabilizes at its plateau values.

Confirmation of the importance of the charge pack in the PAGD function of the present circuitry here considered, comes from the fact that the size (the number of cells) and the intrinsic capacitance of the charge pack affect the PAGD frequency dramatically (see Table 4): increasing the charge pack size of 29 cells to 31, by 7% leads to a 10-fold reduction in frequency; further increases in the number of charge pack cells extinguishes the phenomenon. On the upper end of the scale, this effect appears to be tied in to restrictions that it places on the ability of the larger charge packs to accept the discharge power output once the charge pack voltage exceeds the PAGD amplitude potential. All of these measurements were conducted with the same 128 cm^2 plate PAGD generator, at a pressure of 0.8 Torr and in the triode configuration (see FIG. 9).

Other factors can also affect the frequency: the motion of external permanent magnetic fields oriented longitudinally with the interelectrode gap, external pulsed or alternating magnetic fields, external electrostatic or electromagnetic fields, specific connections of the earth ground, and the presence of a parallel capacitative, capacitative-inductive or self-inductive arm in the circuit, such as we have described for our electromechanical PAGD transduction method as described in the '531 application.

Analysis of the modulation of PAGD amplitude is simpler than that of its frequency, because fewer factors affect this parameter: (1) magnitude of the applied potential, (2) interelectrode gap distance and (3) the negative pressure, as shown in the '863 application, for "low" applied currents. As the magnitude of the applied potential itself is limited by the gap and the pressure, to the desired conditions of breakdown, the important control parameter for the PAGD amplitude is the pressure factor. This is shown in FIGS. **6** and. **7**, respectively for "low" (5 mA) and "high" (~500 mA) applied currents and for the same plate diode configuration of a H34 Al 128 cm^2 plate PAGD generator (5 cm gap), in the simple circuit described in the '863 application; it is apparent that both positive and negative components of the amplitude of these pulses in the oscillograph, are a function of the pressure, but the maximum cut-off limit of our equipment, for the negative component (at 240 volts for the "low" current experiment and at 120 volts for the "high" current), precluded us from measuring the peak negative voltage of these pulses. However, rms measurements of the pulse amplitude at the plates and DC measurements at the circuit output to the charge pack indicate that the negative component increases with decreasing pressure to a maximum, for a given arrangement of potential and gap distance; no pressure-dependent bell shape variation of the pulse amplitude, as that seen for the positive component at "high" applied currents (FIG. **7**) is observed with the negative amplitude component. For the typical range of 0.8 to 0.5 Torr, the rms value for pulse amplitude varies from 320 to 480 volts, for a 5.5 cm gap distance and applied DC voltages of 540 to 580. PAGD amplitude is a critical factor for the design of the proper size of the charge pack to be utilized in the optimal circuit.

The development of the circuits to be described stemmed from fundamental alterations to the principles implicit in our previous methods of electromechanical transduction of AGD plasma pulses as described in the '531 application. Whereas this electromechanical coupling (capacitative and self-inductive), utilized directly, energizes the AGD pulses inverted from the DC input by the vacuum generator, the purpose of the development that led to the presently described experiments was to capture efficiently, in the simplest of ways, most of the pulse energy in a closed circuit, so that power measurements for the energy transduction efficiency of the observed endogenous pulsation could be carried out. Ideally, comparative DC power measurements would be performed at both the input and output of the system, taking into account the losses generated across the components; this would obviate the measurement problems posed by the myriad of transformations implicit in the variable frequency, amplitude, crest factor and duty-cycle values of the PAGD regime, and necessitated some form of rectification of the inverted tube output. From the start our objective was to do so as simply as possible. Early circuits utilizing half-wave rectification methods coupled in series to a capacitative arm (for DC isolation of the two battery packs), with the charge pack also placed in series, showed marginal recoveries of the energy spent at the PAGD generator input. Attempts at inserting a polar full-wave rectification bridge led, as shown in FIG. **8**, to the splitting of the capacitor into capacitors **C3** and **C5**, at the rectification bridge input, and capacitor **C4** in series with both capacitors, all three being in a series string in parallel with the PAGD generator. Under these conditions a DC motor/generator could be run continuously in the same direction at the transversal output (**U1** and **U2**) of the bridge; but if this inductive load was replaced with a battery pack CP (charge recovery pack), either the parallel capacitor **C4** had to remain in the circuit, for the diode configuration or, less desirably, a further capacitor **C6** could replace **C4** and connect one electrode, preferably the cathode C, to the axial member of the discharge tube T, thus resulting in a first triode configuration as actually shown in FIG. **8**. Energy recovery efficiencies of the order of 15 to 60% were obtained utilizing **C6** in this manner, but measurements of the potential and currents present at the output from the rectifier bridge were substantially lower than those obtained using optimal values of **C4**. Effectively, under these conditions, much of the power output from the tube was never captured by the output circuit formed by the second, right hand arm of the system and, being prevented from returning as counter-currents to the drive pack DP by diodes **D1** and **D4**, was dissipated and absorbed by the interelectrode plasma, electrode heating and parasitic oscillations.

Solutions to this problem were explored using the circuit shown in FIG. **9**, which still maintains the necessary communication link for the quasi-sinusoidal oscillation of the capacitatively stored charges at the input and outputs of the rectification bridge, but integrated the functions of capacitor **C4** into the single rectification circuit, in the form of an asymmetric capacitative bridge **C7***a* and **C7***b* placed transversally to the capacitative bridge formed by **C3** and **C5** and in parallel with the charge pack CP at the output from the rectification bridge **D5**, **D6**, **D2**, **D3**. This second capacitative bridge is so disposed as to have its centre point connected to the anode A through capacitor **C5**. If the axial member of the Tube T were to connect to the junction of **D2** and **D3** instead of at the junction **D5**–**D6**, the function of bridge **C7***a* and **C7***b* would be connected to the cathode C through capacitor **C3**. The capacitative bridge is insulated from the charge pack whose voltage it stabilizes, by rectifiers **D7** and **D8**, which also prevent leakage of charge across **C7***a* and **C7***b*. The anode and cathode oscillations generated by the electrostatic charge transduction through **C3** and **C5** into the poles of the charge pack are trapped by the transversal transduction of the **C7** bridge, at the outputs from the rectification bridge, of which the oscillation has to become split between the bridge inputs into half-waves, for electrostatic transduction and full wave rectification to occur. In fact, under these conditions, removal of the **C7** bridge will suppress the PAGD phenomenon, unless other circuit variables are also altered. The transversal bridge is thus an essential piece of this novel circuit. Variations in the circuit as shown in FIG. **10** were then studied, the first two being selectable utilizing switch **S2** (FIG. **9**).

The presence of the capacitative bridge effectively reduces the dynamic impedance of the charge pack CP so that the output circuit approximates to a characteristic in which it presents a very high impedance to the tube T at potentials below a certain level, and a very low impedance at potentials above that level.

With this modified circuit, more effective recovery of the energy produced by collapse of the PAGD pulses is possible, with more effective isolation from the input circuit utilized to trigger the pulses. Under these conditions, the energy captured by this circuit at the output, is not directly related to that utilized in triggering the pulses from the input. The attainment of this condition critically depends on the large capacitance of the transversal bridge being able to transfer the output energy from the tube T into the charge pack CP. Under these conditions, we have found, as will be shown below, that the large peak pulse currents released by collapse of the PAGD pulses released more energy than is used to trigger them, and these findings appeared to tally with other observations (abnormal volt-ampere characteristics and anomalous pulse currents, etc.) associated with the anomalous cathode reaction forces that accompany the auto-electronic emission-triggered PAGD regime. Experiments so far indicate that the power output can be increased proportionately to the series value of C3, C5 and the two identical C7 capacitors.

The circuit of FIG. **10** can be integrated with a circuit such as that disclosed in the '863 application as shown in FIG. **11**, in which a part of the energy recovered can be shunted by the switch S4 into an induction motor M1 having rotor R, to a degree determined by the adjustment of potentiometer R4 and the value selected for C4.

The circuit of FIG. **11** can be further developed as exemplified in FIG. **12** to include configurations which provide switching permitting interchange of the functions of charge packs and the drive packs, it being borne in mind that the nominal potential of the drive pack must be substantially higher than that of the charge pack, the former needing to exceed the breakdown potential of the tube at the beginning of a PAGD cycle, and the latter to be less than the extinction potential.

FIG. **12** essentially represents a duplication of the circuit of FIG. **11**, the two circuits however sharing two identical battery packs BP1 and BP2, and being provided with a six pole two way switch, the contact sets of which are identified as S1, S2, S3, S4, S5 and S6. When the contacts are in position A as shown, battery pack BP1 acts as a drive pack for both circuits, with the upper half (as shown) of the battery pack BP2 forming the charge pack for the upper circuit, and the lower half forming the charge pack for the lower circuit. When the pack BP1 is at least partially discharged, the switch is thrown so that contacts move to position B, which reverses the function of the battery packs thus allowing extended operation of the motors in each circuit each time the switch is thrown.

Based on the manufacturer's data, and using current values within the range of our experimentation as discussed in the next sections, an optimal discharge cycle for a fully charged 6.0 Ahr battery pack at 0.300 A draw is 20 hours, as claimed by the manufacturer, and this corresponds to a cycling between 100% (12.83 V/cell open circuit and load start voltage) and <1% (10.3 V/cell load voltage) of the battery's absolute charge capacity. Even though the discharge mechanism is a time cumulative process with a log function, the discharge can, within 4 to 5 hour time segments (or periods with 20–25% of the full range), be regarded as practically linear with time. This trait, or linearization of the discharge slope, becomes more marked with advancing age and decreasing absolute storage capacity of the cells.

The proportionality between open circuit voltage and the percentage of residual relative capacity for these cells when new (uncycled and not yet aged) is uniform over 98% of the permissible charge capacity withdrawal; in practice this translates into a slope that becomes steeper with time, while the absolute storage capacity diminishes. In turn, this decreasing absolute capacity of the cells results in shorter load discharge times and their further linearization.

A circuit in .general accordance with FIG. **9**, employed in the studies reported in this and the following sections, utilizes a drive pack of 46*12 V Lead acid gel-cells each with a 6.0 Ah rating, and a charge pack with 28 or 29*12 V identical cells. The charge pack was cycled anywhere from 11.2 V to 12.8 V/cell (open circuit voltages), within the proportional region of the relative capacity slope, to yield a capacity increment in the order of 50% (e.g. from 20 to 70%), anywhere within the range of 2 to 100% of its total charge capacity, assumed for now as invariant. The charging process, hereinafter referred to as a PAGD run, took about 20–30 minutes under optimal conditions. The drive pack typically consumed, in the same period of time, 4 to 11% of its initial total capacity , its open circuit voltage typically falling 0.1 to 0.2 V per cell after a PAGD run, within the open circuit range of 12.8 V/cell (100% relative capacity) and 11.2 V/cell (~2%). At the 100% capacity benchmark, the drive pack would theoretically have 20 h*46 cells*12.83 V/cell*0.3 A=3.5 KWh, and the charge pack, for example, 20 h*29*12.83 V/cell*0.3 A=2.2 KWh. Since the capacity per cell is linear with the open circuit voltage within the proportional range, as claimed by the manufacturer, we projected the open circuit voltage intercepts on the manufacturer's proportional curve in order to determine the residual percentage of the total relative capacity and the standard hours of operation left, from any experimental open circuit voltage measurements.

Three pulse generators (2*128 cm^2 and 1*64 cm^2 plate areas) were employed in these studies; they were operated in PAGD runs at 1–120 pulse/second rates, within a negative pressure range of 0.2 to 0.8 Torr and with applied direct currents of 0.2 to 0.6 A.

Both drive and charge packs utilized cells which were bought new at the same time and had initial charge values of 12.4 to 12.55 V/cell (open circuit). These batteries are capable of energy densities of 33–35 Whr/kg. However, the experiments shown in Table 5 are selected from a series that spanned nearly 12 months, beginning 6 months after purchase; hence, loss of absolute storage capacity by the batteries had occurred in the intervening time, as a function of both age and charge/discharge cycle life.

Measurements of the open voltage of either drive (D) or charge (C) (see column 2, Table 5) packs for 8 separate experiments, all utilizing the triode configuration, were performed before (b) and after (a) a PAGD run (see columns 3 and 4), at either 15 or 30 minutes (see column 26) of the open circuit voltage relaxation after a PAGD run was terminated. Corresponding open circuit voltages per cell are shown in column 5, and the percentages of the predicted total relative charge capacity resulting from the intercepts on the manufacturer's proportional curve are shown in column 6, Table 5. Equivalent maxima for the theoretical hours of operation left are shown in column 7, the percentage change in relative capacity arising as a consequence of either charge pack charge capture (capacity gained) or of drive pack output (capacity lost) is shown in column 8. Translating the intercepts into power units yields the values shown in column 9, Table 5, for total kWh left in each pack before and after PAGD production, those shown in column 10 for the actual power gained and lost during the periods of operation (presented in column 12) and those shown in column 13 for the power predicted to be gained or lost per hour of PAGD production. On the basis of the experimental open voltage values and their intercepts, the predicted net kWh values per hour of PAGD energy production (after deduction of measured losses) and the corresponding experimental breakeven efficiencies (where breakeven=100%) are presented, respectively, in columns 14 and 15. The PAGD frequency per second is shown in column 11; the number of 12 V cells, in column 16; the tube ID, in column 17; the cathode (and anode) area (s), in column 18; the plate material, in column 19; the input ballast utilized (**R1**, FIG. **9**), in column 20; the size of each capacitor (**C3** or **C5**) of the tube output bridge, in column 21; the size of each capacitor (**C7***a* or **C7***b*) of the transversal capacitative bridge, in column 22; the status of **S4** and thus, of the parallel and auxiliary electromechanical arm (see FIG. **11**), in column 23; the negative air pressure in column 24; the gap distance between the plates, in column 25; and columns 27,28 and 29, show the status of the elements of the switched on parallel electromechanical arm of the circuit—the parallel **C4** capacitor, the motor input resistor **R4** and the motor revolutions per minute (measured stroboscopically), respectively.

From these figures of Table 5, and utilizing the data for the two first examples shown, we calculated the predicted performance of the system based on the open voltage measurements. In the first example, where the system was run continuously without interruption, the charge pack increased the percentage of its total capacity by 43% (a two-fold increase in capacity) and, during the same period, the driver pack decreased the percentage of its total capacity by 7% (a ~10% decrease in capacity relative to the percentage of residual total capacity at the start, i.e. 77%) (cp. columns 6 and 8, Table 5). Subtracting the predicted initial total energy (0.835 KWh) available to the charge pack before the experimental run (first line of column 9, Table 5) from the predicted total energy (1.823 KWh, second line of column 9) available to the charge pack after the PAGD charge run, gives us the total energy gained by the charge pack: 0.988 KWh (column 10) in 21.5 minutes (column 12) of continuous PAGD performance. Conversely, subtracting the predicted final total energy (2.4 KWh) available to the driver after the experimental run (fourth line of column 9, Table 5) from the predicted total energy (2.66 KWh, third line) available to the driver before the PAGD charge run, gives us the total energy lost by the drive pack: 0.26 KWh in 21.5 minutes. If we divide the total available energy gained by the charge pack, by the total energy lost by the drive pack, we obtain a surplus factor of 3.9×, or 388% of the breakeven point (column 15). The same values result from dividing the charge pack % of total capacity gain by the drive pack % of total capacity lost, and then downscaling this value by multiplying it by the typical scale factor for the two packs, 29/46=0.63×.

In an analogous fashion, we analyzed the results for the second example shown in Table 5. Here, the charger increased the percentage of its total capacity by 45.5% (a 22.75 fold increase in estimated total relative capacity) and, during the same period, the driver decreased the percentage of its predicted total capacity by 7% (a ~17.5% decrease in capacity relative to the percentage of residual total capacity at the start, i.e. 40%). By dividing the predicted total available energy gained by the charge pack (0.962 KWh/18 minutes) by the expected total energy lost by the driver pack (0.246 Kwh/18 minutes) we obtain a surplus factor of 3.9×, or 391% of the breakeven point. This corresponds to an interrupted, total sequential run of 18 minutes, each minute-long run being separated by a cooling and voltage relaxation period of 15 minutes before the next run is carried out, at an average PAGD frequency of 61 PPS.

Analysis of the remaining results illustrates how a number of PAGD controlling parameters interact to determine conditions for effective maintenance of a PAGD regime. The lower gain and higher loss per unit time registered for the third run of Table 5, which results in the lower breakeven efficiency of 230% and a smaller net power production rate than before (power estimates of 1.396 kWh/h of PAGD operation vs 2.387 kWh/h, for the second run, Table 5) illustrate, for example, the combined effect of lowering the pressure (0.8 to 0.7 Torr) and running the PAGD continuously (the heating effect), both of which depress the PAGD frequency. The fourth run of Table 5 identifies the continuous performance of a "broken in" softer grade of aluminum (column 19), having a lower work-function (as determined from the higher PAGD frequency spectrum) than the harder H34 plates of the previous examples, and shows that, despite the series value of the total capacitance being higher (5,333 mfd vs 4,030 mfd for runs one through three), and despite the higher vacuum (0.2 Torr), the lower work-function results in a higher frequency; however, even though this run registers a predicted higher breakeven efficiency (310%) than the previous experiments, these conditions result in a 4/5-fold lower estimate of net power produced, when compared to the previous three PAGD runs.

PAGD runs 5 and 6, Table 5, illustrate the effect of switching on the auxiliary electromechanical arm of the circuit shown in FIG. **11**. Increasing the amount of charge capacitatively shunted into the electromechanical arm by higher **C4** values (column 27), and increasing the current that feeds the squirrel cage induction motor utilized by lowering **R4** (column 28), results in a power capture by the charge pack that registers an energy loss (predicted to be 96% efficient, falling short 4% of breakeven recovery), as most of the tube output power is spent in the electromechanical arm and its motor effect. Furthermore, under the conditions of maximum electromechanical action, the drain imposed on the drive pack becomes considerable (see loss in columns 10 and 13), even if the **C3** and **C5** values are reduced, column 21, Table 5). These runs also illustrate how the motor appears to function as an electrical induction generator having rpm values much higher than the synchronous values prescribed by the frequency of the PAGD (column 29, Table 5).

The extremely large breakeven efficiency of PAGD run 5, Table 5, indicates that with selected values of **C4** and **R4**, it is possible to operate the motor in the auxiliary arm and still accumulate excess energy from the PAGD production in the charge pack.

Runs 7 and 8 illustrate results obtained for 64 cm^2 plates, and a shorter interelectrode gap distance, for two pressures (0.8 and 0.5 Torr), the device being open to a rotary pump manifold in the first instance and sealed from the pump, in the second case. Despite the lower vacuum, the higher pulse frequency (32 vs 5 PPS) and breakeven efficiency (906% vs 289%) registered by run 8 when compared to run 7, are a consequence of the method of run 8, which was interrupted systematically by 5 passive cooling periods, as in the case of run 2, whereas run 7 was continuous. This again resulted in higher average PAGD frequencies (at lower pressures), a predicted two-fold greater gain and a predicted two-fold smaller loss (columns 13 and 14) for run 8.

FIG. **13** shows curves representing the slopes of the open circuit relaxation voltages, which are linear with the log of time elapsed from cessation of discharge, for both drive and charge packs, in the same run 8 set out in Table 5. The experiment in its entirety consisted of preliminary resistor-loaded measurement discharges and their corresponding open circuit voltages from the moment of cessation of the resistive discharge (illustrated, respectively, by the open squares of **DPT1** for drive pack relaxation time **1**, and by the open circles of **CPT1** for charge pack relaxation time 1), followed by their relaxation rates in the wake of the PAGD production (the hatched squares of DPT2 for drive pack relaxation time **2**, and the hatched circles of CPT2 for charge pack relaxation time 2), and finally, by the relaxation rates from the final resistor-loaded measurement discharges (the black squares of DPT3 for drive pack relaxation time **3**, and the black circles of CPT3 for charge pack relaxation time **3**). Discharge resistances were 833 ohms for the charge pack, and 2083 ohms for the drive pack in all cases, corresponding to resistors **R3** and **R2**, respectively, of FIG. **9**. This methodology will be examined in greater detail below. It is apparent that, after every load period, be this resistive (**CPT1, DPT1,** CPT3 and DPT3) or due to PAGD operation (DPT2), the relaxation slope is positive; as shown from slopes **CPT1** and **DPT1**, the log time proportionality of the open circuit voltage relaxation, under these conditions, tends to plateau after ~30 minutes. The exception to this general behaviour lies in the voltage relaxation slope CPT2, which is negative and reflects the charge accumulation occurring in the charge pack and obtained by capture of energy produced during PAGD operation, triggered by the energy drawn from the drive pack during load time **2**.

As a first approximation of electrical power generated and consumed by the energy conversion system of the invention, the previous open circuit voltage method is of significance in showing the basic trends involved in interaction of the operating parameters. However, in all likelihood, it overestimates the actual values of electrical power consumed and generated, for a variety of reasons. First, it assumes that the relative capacity scale of the batteries in the drive and charge packs is an absolute charge capacity scale with an invariant maximal charge retention, which it is not; in fact, the absolute charge capacity is itself a variable subject to several factors, such as the cycle life, overcharging or undercharged conditions, cell age, residual memory and the rate of charge and discharge. Hence, the inference of a uniform time scale on the basis of the open circuit voltage/capacity intercepts may not be warranted. Finally, it does not integrate the open voltage decrease over time, and utilizes the specification load current as the average current over time.

In order to obviate these problems, we resorted to a variety of other measurement methods. First, we proceeded to compare the closed circuit, preliminary, resistive-load discharge measurements for either charge or drive pack, under conditions of negligible loss of power, as these measurements were statistical means (n=9) taken, at equal intervals, during the first 90 seconds of the load discharge, and obtained both just before the PAGD production runs (but separated from each PAGD run by an open circuit voltage relaxation of 30 minutes) and just after the runs (but equally separated by a relaxation of 30 minutes). As an example of the data generated by such an approach, FIG. **14** illustrates the shift of the slopes indicating marginal power loss for the drive pack (from the closed squares to the open squares) and those indicating gain of power for the charge pack (from the open circles to the closed circles), in actual total load power values.

Integration of these power measurements over the projected load discharge time, taken from the family of curves generated on the basis of the manufacturer's load voltage over discharge time specifications, led to a direct comparison of the new values, as shown in Table 6, with the values presented in Table 5, for the first three instances introduced. All values of Table 6 were obtained by resistive measurements of power that entailed a negligible power loss. Table 6 confirms the fundamental equivalence of runs 1 through 3, as already seen from their corresponding analysis using the open voltage method (see runs 1 to 3, Table 5). This new power estimation method also confirms the lower loss encountered in run **2** utilizing interrupted PAGD operation. While the breakeven efficiencies sensibly doubled using this method, the estimates of actual electrical power consumption recovery decreased by a 2 to 3-fold factor. Thus this direct load voltage/amperage measurement method of estimating actual power losses or gains, is a check upon the open voltage method previously utilized.

Direct, instantaneous measurements of the voltage and current characteristics of the PAGD production and capture phenomena being discussed, were also performed during PAGD runs for diverse sets of conditions, including all those described in the two previous sections. In Table 7 we show these results for two PAGD generators having an identical electrode area (128 cm^2) and connected to electrical energy capture circuits of three separate configurations as set forth in FIGS. **10A, 10B** and **10C** and column 2, Table 7. In the configuration of FIG. **10C**, or double diode configuration, both electrode plates act as cathodes and the axial member as the anode collector (experiments 1–4, for the **H220** device and 13–14, Table 7, for the **H34** device). In the configuration of FIG. **10B**, or triode configuration, one plate acts as the cathode, the axial member as an auxiliary cathode and the other plate as a collector (experiments 5–9, Table 7). In the configuration of FIG. **10A** or single (plate to plate) diode configuration, the axial member is disconnected, and the polarity of the plates remain as in the triode configuration (experiments 10–12). All measurements were taken after 1 minute of PAGD operation of the devices, which were, at the start of each run, at room temperature. All cathodes had been previously broken in with $>2*10^6$ AGD pulses. The open circuit voltage of the charge pack was, for all cases, at 359 to 365 volts, before each test. The direct measurements of the PAGD input and output DC voltages and currents were obtained as statistical means of 10 second long measurements, and at no time did the standard error of the plate voltage mean exceed 35 volts.

The air pressure within the tube during these tests is shown in column 3, Table 7, the drive pack DC voltage (X), in column 5, the DC voltage across the plates (Y), in column 6, the drive pack output current (PAGD input current), in column 7, and the drive pack total watts output is shown in column 8. Columns 9 and 10 show the PAGD voltage (PAGD $V=(X-Y)/I_{av}$) and the value of the PAGD extinction potential in V/cm. The recovery co-ordinates (ie the PAGD output energy) found at the **U1–U2** output (FIG. **9**), are shown in columns 11 to 13, as the charge pack's E1–E2 input DC voltage, amperage and power watts, respectively. The calculated resistance of the entire circuit is given in column 14, the registered PAGD frequencies in column 16, and running conditions in columns 17 to 18. The breakeven efficiency obtained by direct comparison of the electrical power figures for the drive and charge packs, respectively, is given in column 15. This assumes, for purposes of a generalization of power production rates over time, that the quasi-instantaneous, direct measurements here obtained can be translated to outputs obtained per unit time, and thus into direct Watt-hour measurements.

Data from runs 1 through 4 demonstrate that, at these PAGD frequencies, there is no difference between using fast switching (32 nanoseconds) MUR 860 diodes, or regular 40HFR-120 silicon diodes, in the rectification bridge of the electrical energy capture circuit, and that the PAGD frequency varies as a function of decreasing air pressure.

Runs 5 to 14 show that, in general, for the same tube, the single and double diode configurations are the most efficient, for the same pressure, the diode configuration typically yields $\sim$1.5-2x larger breakeven efficiencies (cp runs 10–11 and 13–14, with runs 5–9, Table 7). The largest accumulations of power are also registered in the diode mode(s). This trend appears to be a function of the much lower cathodic work-function of the aluminum plates, than of the tungsten of the axial member utilized as an auxiliary cathode in the triode configuration. A feature of the data from these 14 different runs is the consistent excess power outputs (column 15, Table 7) and their narrower range (218 to 563%), when compared to those observed with the previous two methods of experimental analysis.

Run 12, Table 7, shows that the switching on of the electromechanical arm can be performed without entailing a power loss in the PAGD capture circuit, as previously found for run 5, Table 5, utilizing the open circuit voltage method. In fact, with C4=8 μF and R4=500 ohms, the AC induction motor behaves as an electrical flywheel (eg. 2800–3000 rpm for 10 PPS inputs), while the electrical energy capture circuit still registers a sizeable excess electrical power production (compare runs 11 and 12, Table 7). Runs 13 and 14 illustrate how the charge pack's state of charge and its inherent capacitance affects both the PAGD frequency and the power producing efficiency of the entire system: as the charge pack is reduced from 29 to 19 cells, the PAGD generator adjusts by reducing its frequency logarithmically and, while the charge pack input current is greater than before, the drive pack loss becomes still larger and the breakeven efficiency much lower (by $>\frac{1}{2}$, from 563% to 228%). This is because the circuit must translate the naturally larger PAGD amplitude into a larger surplus of output current, and in this process becomes less efficient.

If the first measurement method employed (the open circuit method) had to make too many theoretical assumptions about the system's performance under load conditions and hence about its effective charge capacity, the second approach still had to suppose an invariant discharge time and thus an invariant absolute charge capacity on the part of the battery systems (charge packs) employed for capture which it approximated by an operation of integral calculus. With the third method described above, theoretical assumptions were avoided except that, in these measurements, the actual performance of a given battery in terms of time, time of delivery and time of capture, was also ignored; no account is taken of the time-dependent modulation of the PAGD frequency, as effected by certain of the parameters analyzed, namely the charge pack state of charge, the method of sequencing the PAGD runs (continuous vs interrupted) and its concomitant heating effects, and the state of charge (load voltage and current capacity) of the drive pack. A simple, non-negligible, resistive measurement of power lost by the drive pack, and an identically non-negligible measurement of the power gained by the charge pack, for the same experiment and the same singular time of PAGD production, were performed repeatedly to corroborate the previous three approaches. For this purpose, all experiments were designed as a continuous series of sequential phases:

1) before a PAGD run, a resistive discharge was measured across either pack over periods of 1 to 3 hours (utilizing the DP and CP resistances previously reported in the open voltage section) and followed by a 15 to 30 minute open circuit voltage relaxation;

2) then, the PAGD runs were performed, either continuously or as interrupted, composite sequences, and the corresponding open circuit relaxation voltage(s) were measured, after the cessation of the integral PAGD run;

3) finally, resistive discharge measurements, obtained under identical conditions to those recorded before the PAGD run, were carried out for either pack, followed by concomitant battery voltage relaxation rate measurements.

Under these experimental conditions, exact power measurements could be taken from an analysis of the actual battery discharge curves before and after the PAGD run. Based on a comparison of the curve trends of the pre-run resistive discharge of the drive pack with those of the post-run resistive discharge, the effective power drawn (ΔE_c) from the withdrawable power capacity of the drive pack incurred during a PAGD run, was ascertained. This represents the power consumption during the run, and the experimental value thus recorded constitutes the actual power figure that must be matched for breakeven ( ) to occur. Hence, the breakeven value equals, by definition, the electrical energy input to the system. Similarly, a comparison of the charge pack pre-run and post-run resistive discharge curve trends identified the effective power (ΔE_ρ) added to the withdrawable capacity of the charge pack. This quantity represents the electrical energy recovered during the run. The relation for the two quantities is expressed by the breakeven efficiency (BE= %) equation:

$$\% = \Delta E_\rho / \Delta E_c \cdot 100$$

If the breakeven efficiency is less than %=100, then the apparatus registers a net loss in electrical energy in the CP with respect to the DP. Conversely, if %>100, then there is a net gain in electrical energy in the CP, as compared to that lost in the DP. For purposes of this analysis, a limit to the minimum withdrawable capacity was placed, from experiment and in agreement with the load current curves of the manufacturer, at 115 W for the driver pack (average current of 0.250 A, minimum current of 0.230 A), and at 90 W for the charge pack (average current of 0.375 A, minimum current of 0.334 A), as a function of both their total cell size (respectively, 46:29) and the difference in the resistive loads employed for the discharge measurements. All cathodes had been broken in, as described before.

The results obtained with this fourth method, for six selected experiments with three diverse types of devices (using different electrode plate areas, gap lengths, and electrode work-functions), configured both in the triode or the (single) diode (e.g. FIG. **10**B) arrangements, at the indicated pressures, are presented in Table 8. In all cases, a net excess of combined battery pack charge, expressed as electrical watt hours, is registered (columns 8 and 10, Table 8) and the breakeven efficiencies are all >100% (column 10). Experimental groups #**1** and #**2** again demonstrate that, for the same cathode, the interrupted PAGD sequence method of group #**2** (1 minute of PAGD function, followed by a 15 minute relaxation, and so on) yields a higher breakeven efficiency because of the lower losses registered with this minimal plate heating method (column 10, Table 8). Group #**3**, Table 8, shows that the PAGD power production efficiency is also higher for a lower work-function cathode material (**H220** vs **H34**), being subjected to PAGD auto-electronic conditions at a 4-fold lower pressure than the control groups #**1** and #**2**; however, the lower pressure depresses the frequency and, together with the interrupted PAGD sequencing method, it also lowers the loss, causing an actually much larger breakeven value than registered for the previous two groups. Groups #**4** and **5** exemplify the dual effect of lowering both the plate area and the gap distance: the former affects the PAGD event frequency, whereas the latter affects the PAGD amplitude, and thus the capture efficiency of the charge pack. Despite a cathodic work-function practically and operationally identical to that of groups #**1** and **2**, these smaller plate area and shorter gap devices utilized in groups #**4** and **5**, yield 3- to 6-fold lower net power outputs, as well as lower breakeven efficiencies, than the former groups, at the same pressure. Finally, group #**6** exemplifies the results obtained for the plate diode configuration, where the frequency is lower (no triggering role for the axial member), and a higher loss leads to the lower breakeven efficiency, comparable to that of the lower area and shorter gap groups #**4** and **5**.

In order to verify the discharge curve lengths employed in these analyses and experimentally establish the actual charge capacity of the battery packs, calibration resistive discharges, between the maximum charge state and the minimum limits chosen, were performed for each pack with their respective discharge resistances R2 and R3 (see FIG. **9**). These discharge calibration curves were plotted for half maximal charge values shown in FIGS. **15**A and **15**B, and from the curve produced, we have determined the total half-charge capacities of each battery pack to be 1.033 kWh (100%=2.066 kWh) for the drive pack and 660 Wh (100%=1.320 kWh) for the charge pack. Based upon the corresponding maximal (100%) capacity values, we determined the actual percentages of the relative charge capacities shown in column 5, Table 8, which correspond to the experimental values obtained. We also noted that the curves plotted showed two quite distinct time linear slopes, the slope of the delivery of power per time unit steepening very markedly at the approach to the limits of the permissible withdrawable capacity, occurring at 115 W into R2, and 90 W into R3.

The pre-PAGD run and post-PAGD run, drive and charge pack discharge curves corresponding to groups #3 and #6, respectively for triode and plate diode configurations, in Table 8, are shown in FIG. **16** (drive pack) and **17** (charge pack), for group #3, and in FIG. **18** (drive pack) and **19** (charge pack), for group #**6**. In all cases, the open symbols represent the pre-PAGD run discharge curves, whereas the closed symbols represent the post-PAGD run discharge curves.

As a further check on these values, a videographic, millisecond analysis of the singular power simultaneities occurring at both ends of the system (drive and charge packs) was performed for various 10 second samples of diverse PAGD runs. A typical example is shown in FIG. **20**, which is a sample of the PAGD run designated as #**6** in Table 8. Whereas the drive pack DC wattage spent as input to PAGD production varied from 36.6 to 57.82 watts, by a factor of 1.6x, the DC wattage entering the charge pack as captured PAGD output varied more pronouncedly by a factor of 2.7x, from 146.4 to 399.6 watts (all meters were in the same selected ranges of voltage and current) with the semi-periodic, intermittent character of each singular emission, though within specific, ascertainable ranges for both amplitude and current outputs. Assimilation of the singular behaviour of the PAGD in this sample, by a statistical treatment of its variation (n=64), indicates that the operational breakeven efficiency observed during this sampled period lies at 485.2%±18% with projected 48.3Wh drive pack loss and 221.7Wh charge pack gain. This matches rather closely the observed 483% breakeven efficiency, and the 37.7Wh loss as well as the 182.2 kWh gain for the overall PAGD run reported in group#**6**, Table 8, and indicates how close are the values obtained by the operational and extensive non-negligible resistive discharge power measurement methods employed.

Finally, an example of the correlation between the drive pack PAGD load voltage and the charge pack PAGD charging voltage, as a function of the duration of the intervening PAGD run between resistive discharge measurements, is shown in FIG. **21**, for the PAGD run corresponding to group #**4**, Table 8.

Using the same pulse generator with H200 AL 128 cm^2 plates, in a double diode configuration, and the same circuit values (but with CP=23 cells), three experiments were conducted at different PAGD frequencies, as a function of varying air pressure. Analysis of driver pack losses and charge pack gains by the extensive load discharge measurement method, as described before, led to the determination of the gross and net gains (respectively, without and with losses included) per pulse, in milliwatt-hour, for each frequency, as well as of the gross and net power gains per second of PAGD operation. The results are shown in Table 9. Even though the gross and net gains of power per pulse were observed to increase with decreasing frequency, the gross power gain per unit time increased with increasing frequency. However, this last trend does not necessarily translate into a higher net gain per unit time, because the losses in the driver pack (not shown) also increase significantly with PAGD frequency. These losses are in all probability related to more energy retention by the plasma at higher frequencies when plasma extinction becomes incomplete. We expect net gains to reach optimal thresholds for any given type of circuit configuration set of values and pulse generator dimensions.

Certain additional observations made during experiments with the double diode configuration of FIG. **10**A may assist in understanding of the invention.

1) Replacing residual air with argon gas leads to higher PAGD frequencies, as noted by us when utilizing a 128 cm^2 H200 AC plate pulse generator in the double diode configuration ($V=575$). At 1 Torr, the pulsation rate went from 20 PPS in air to 1300-400 PPS in argon. With 29*12 v cells in the charge pack, input currents ceased to flow into it. Under these conditions, the tube potential across the plates decreased and the drop across the input resistor increased. The value of $E(=V/d)$ became smaller (gap size = 3 cm from plate to axial anode collector), as the extinction voltage decreased.

2) With frequencies of 400 PPS, the currents flowing into the charge pack fell to zero. Replacing a fast-recovery type HFR 120 (1200v, 40A) diode bridge by a type MUR 860 (600v, 8A) diode bridge had no effect. When the amplitude of plate potential oscillations falls below the potential of the charge pack, there is also a tendency to produce arc discharges. For output currents from the vacuum pulse generator to enter the charge pack, the number of cells must be reduced so that the potential of the charge pack is low enough to admit the transduced currents. A reduction from 29 to 23 cells allowed currents of 250 mA to enter the CP, and further reduction to 19 cells doubled these currents (per polarity arm).

3) Our observations show that it suffices under these conditions (CP = 19 cells) to increase the vacuum, so that the frequency decreases, and the plate potential and the charge pack input currents increase. At 0.1 Torr, the currents reached 1A D.C. per plate, and at 0.05 Torr, 2A D.C.

The interconnection between these factors indicates that the extinction voltage is a function of the PAGD frequency: the higher the PAGD frequency, the lower the extinction voltage, until empirical (in distinction from predicted) VAD field values are reached. As a consequence, the start voltage of the charge pack must be adjusted, by varying the number of cells composing it, so that it lies below the lowest extinction voltage of the PAGD, for any given geometry and gap distance.

Secondly, as the ion plasma is made more rarefied, the frequency of the emissions decreases, but the peak values of the output voltage and current per pulse increase. The slower the PAGD and the more rarefied the atmosphere, the higher is the output energy produced by the system relative to the input energy.

Autographic analysis of PAGD-induced cathode craters in **H34** plates was performed, and their average inner diameter and maximal depth were determined. Similar studies were performed for PAGD-induced craters in Alzak (trade mark) plates. The secondary craters characteristically found in Alzak plates, along fracture lines irradiating from the main crater, are absent in **H34** plates; instead, in **H34** plates, one observes a roughened surface surrounding the emission crater, quite distinct from the original rough aspect of the pulled finish of these hardened aluminum plates. Also unlike the Alzak main craters, the **H34** craters often have a convex center occupied by a cooled molten metal droplet, whereas the Alzak craters had a concave, hollowed out aspect. Eventually, as the pitting resulting from PAGD cathodic emissions covers the entire cathode, the metallic surface gains a very different rough aspect from its original appearance. In this process, craters from earlier metal layers become progressively covered and eroded by subsequent emissions from the same cathode. Altogether different is the surface deposition process occurring at the anode; here, the surface appears to become more uniform, through the mirroring and possibly abrasive actions of cathode jets. Macroscopically, with increased periods of PAGD operation, the anode surface appears cleaner and more polished.

With the data obtained by the metallographic method of crater measurement, we estimated the volume of metal ejected from the cathode, by assuming that the crater represents a concavity analogous to a spherical segment having a single base ($1/6\pi*H\ [3r^2+H^2]$, where H is the height of the spherical segment and r the radius of the sphere), while disregarding the volume of the central droplet leftover from the emission. The following are mean ±SEM crater diameters (D), crater depths (H) and maximum volumes (V) of extruded metallic material for two types of aluminum cathodes, Alzak and **H34** hardened aluminum, subject to a high input current PAGD:

1- Alzak: D—0.028 cm±0.003; H—0.002 cm±0.0002; V—$6.2*10^{-7}$ cm^3;

2- H34: D—0.0115 cm±0.0004; H—0.0006±0.0001; V—$3.1*10^{-8}$ cm^3;

Accordingly, utilizing plates composed of either material with 3 mm of thickness, and thus with a volume of 38.4 cm^3 per plate and considering that only ⅔rds of the cathode shall be used (a 2 mm layer out of the 3 mm thickness), the total number of pulses per plate total (TLT) and partial (PLT) lifetimes is theoretically:

1- Alzak: TLT: 6.2*107 pulses; PLT: $4.1*10^7$ pulses;

2- H34: TLT: $1.2*10^9$ pulses; PLT: $8.1*10^8$ pulses.

Typically, an H34 device can produce ~0.25 kWh per 10,000 pulses. The corresponding value for a PLT is thus a minimum of 1.0 MWh/Alzak cathode and of 20 MWh/H34 cathode. As the cathode for each combination is only 66.7% consumed, the vacuum pulse generator may continue to be used in a reverse configuration, by utilizing the other plate in turn as the cathode; thus, the estimated minimal values become, respectively, 2.0 MWh/Alzak pulse generator and 40 MWh/H34 pulse generator. The same rationale applies for the double diode configuration of FIG. **10C**.

We have created a two-ported system for the production of the singular discharge events which we have previously identified in the '863 application as an endogenous pulsatory abnormal glow discharge regime where the plasma discharge is triggered by spontaneous electronic emissions from the cathode. We have examined the functioning of this two-ported system in order to determine what were the electrical power input and output characteristics of a sustained PAGD regime. Despite the wide (10-fold) variations in net power and breakeven efficiencies measured by the four different methods employed (open voltage measurements, time integration of negligible power measurements, operational power measurements and real time non-negligible power measurements), all methods indicate the presence of an anomalous electrical transduction phenomenon within the vacuum pulse generator, such as can result in the production at the output port of electrical energy measured and directly captured which is greater than would be anticipated having regard to the electrical energy input at the input port. With the most accurate of the methods employed we have found typical PAGD power production rates of 200 Wh/hour of PAGD operation, and these may reach >0.5 kWh/h values.

The discrepancies between the methods utilized have been extensively examined in the preceding section.

Our systematic approach demonstrates that the most frequently employed method of measuring the charge capacity of batteries by the open voltage values is the least reliable approach for the determination of the actual net power lost or gained by the battery packs used in the system: when compared to all three other methods, it overestimates net power consumed and produced by up to 10 fold, as well as distorting the breakeven efficiencies, particularly at the extremes of operation. All this results from the grossly diminished (50–60% of manufacturer's theoretical estimate) effective charge capacity of the lead acid gel cells employed, as determined experimentally from FIGS. **18** and **19**, when compared to the theoretical maximal charge capacity values that serve as scale for the open voltage measurements. In other words, the effective energy density of the batteries during these experiments was in fact approximately half of the manufacturer's estimated 30 Wh/kg.

Under these actual conditions of battery performance, the third and fourth methods (respectively, operational and real-time non-negligible power measurements) of power consumption and production proved to be the best approach to measure both PAGD electrical power input and output, as the results of both methods matched each other closely, even though the former is a statistical treatment of simultaneous events and the latter is a real time integration of their cumulative effects. The second method is clearly less reliable than either the third or the fourth methods, and this stems from the fact that the power consumption slopes of negligible resistive discharges not only are very different from the quasi-steady state discharge slopes (beginning at >5–15 minutes) of extensive resistive discharges, but also their proportionality may not reflect the real time proportionality of equivalent prolonged resistive discharges.

The main advantage of the fourth method is that it effectively takes into account the actual time performance of the batteries comprised by the overall PAGD production and capture system we have described. As such, the method may have the main disadvantage of reflecting more the limitations of the batteries employed (their high rate of degradation of the absolute value of total effective charge capacity, and limited efficiency in retaining charge derived from discontinuous input pulses) than indicating the actual power output. There are a number of possibilities for fine tuning of the system introduced by the present work, beginning with the utilization of secondary batteries or other charge shortage or absorption devices that have less variable or more easily predictable actual charge capacity. In this respect, there are two major shortcomings to the batteries used to form the drive and charge packs; (1) their significant memory effect and (2) their design for constant, rather than discontinuous, DC charging. Recently developed Nickel Hydride batteries are an example of an electrostatic charge-storage system that lacks a substantial charge memory effect, and their experimental batteries are being developed currently for higher efficiency intermittent charging methods. Electrostatic charge retention systems having better energy densities, better charge retentivities and insignificant memory effects will probably be more efficient at capturing and holding the energy output by the circuit. In practical embodiments of the invention, effectiveness in charge utilization will be more important than measurability, and any device that will use the energy effectively whilst presenting an appropriate back EMF to the system may be utilized.

The effect of the performance characteristics of the drive and charge packs is only one amongst many parameters affecting operation of the invention. As shown by our extensive investigation of the diverse PAGD phenomenon the recovery of energy from it by electromechanical transduction as in the '531 application, or electrostatic capture as described above, the factors involved in modulating the frequency, amplitude and peak current characteristics of the PAGD regime are complex. Manipulation of these factors can improve electrical energy recovery, or reduce it or even suppress PAGD. We have so far noted numerous factors that affect PAGD frequency and some amongst those that also affect the PAGD amplitude. Aside from these factors, the circuit parameters of the output port portion of the circuit, in addition to the nature and chemical characteristics of the battery cells already discussed, the charge potential of the charge pack, the characteristics of the rectifiers in the recovery bridge in relation to the period of PAGD superesonant frequencies, and the effective values of the parallel and transversal capacitance bridges can all influence the results achieved. Certain factors however have a radical effect on PAGD operation, such as the gap distance and the charge pack potential. Too small a gap distance between the cold emitter (cathode) and the collector will result in an increasing reduction in energy recovery. The potential presented by the charge pack must be less than the voltage amplitude developed by the PAGD, as specified by a given gap distance at a given pressure. Too large a charge pack size with respect to PAGD amplitude and the gap length will preclude PAGD production or result in extremely low PAGD frequencies. In brief, the energy absorption rate and the counter potential presented by the charge pack or other energy utilization device are important factors in the operation of the circuit as a whole, and should either be maintained reasonably constant, or changes should be compensated by changes in other operating parameters (as is typical of most power supply circuits).

Since our test results indicate that the electrical power output of the circuit can be greater than the electrical power input to the circuit, the circuit clearly draws on a further source of energy input. Whilst we do not wish to be confined to any particular theory of operation, the following discussion may be helpful in explaining our observations. These observations have been discussed in some detail so that the phenomenon observed can be reproduced, even if the principles involved are not fully understood.

In the '863 and '531 applications we have identified a novel, cold-cathode regime of vacuum electrical discharge, which we have termed the pulsed abnormal glow discharge (PAGD) regime. This regime, which occupies the abnormal glow discharge region of the volt-ampere curve of suitable discharge tubes, has the singular property of spontaneously pulsing the abnormal glow discharge in a fashion which is endogenous to the tube and its circuit environment that constitutes a vacuum pulse generator device, when it is operated under the conditions we have identified. In fact, when stimulated with continuous direct current, in such conditions, such a circuit responds with spontaneous abnormal glow discharge pulses that enable effective segregation of input and output currents. We have demonstrated electrically, metallographically, oscillographically and videographically, how the pulsed discontinuity results from a self-limiting, autoelectronic cathode emission that results in repeated plasma eruptions from the cathode under conditions of cathode saturated current input. The auto-electronic triggering of the PAGD regime is thus akin to that of the high-field emission mechanism thought to be responsible for vacuum arc discharges (VAD regime). However, under the PAGD conditions we have defined, this mechanism is found to operate in the pre-VAD region at very low field and low input average direct current values, with very large interelectrode distances and in a self-limiting, repetitive fashion. In other words, the PAGD regime we have identified has mixed characteristics: its current versus potential (abnormal glow) discharge curve is not only distinct from that of a vacuum arc discharge, but the electrical cycle of the PAGD regime itself oscillates back and forth within the potential and current limits of the abnormal glow discharge region, as a function of the alternate plasma generation and collapse introduced by the discontinuous sequencing of the auto-electronic emission process. Accordingly, the intermittent presence of the abnormal glow, as well as the observed segregation of the current flows, are due to the diachronic operation of these spontaneous cathode emission foci. The micro-crater and videographic analyses of the PAGD have demonstrated the presence of an emission jet at the origin of each pulse, a phenomenon which VAD theory and experiment has also identified. Metallic jets originating at the cathode spots of VADs have been known to present velocities up to, and greater than 1000 m/sec.

In light of the above, the energy graft phenomenon we have isolated would have to be operated, at the micro-event scale, by the interactions of the cathode emission jet with the vortex-formed impulse-transducing plasma in the interelectrode space. Several aspects can be approached in terms of the complex series of events that constitute a complete cycle of operation, on a micro-scale. There are interactions within the cathode, interactions at the cathode surface, interactions between the emission jet and the plasma globule close to the cathode, and finally, interactions of the resulting electron and ion distributions in the interelectrode plasma, within parallel boundaries.

In general, in the presence of an electrical field, the distribution of potential near the cathode forms a potential barrier to the flow of electronic charge, as this barrier is defined by the energy that the most energetic electrons within the metal, the Fermi energy electrons, must acquire before freeing themselves from the cathode surface potential to originate an emission jet. Before any free electrons become available for conduction in the space adjoining the cathode, they must cross the boundary posed by the potential barrier. With a weak applied field, classical electron emission from a metal can only occur if an energy practically equal to the work-function of the metal is imparted in addition to the Fermi energy. Under thermionic conditions of emission, the heating of the cathode provides the needed energy input. However, the cold-cathode Fowler-Nordheim quantum-field emission theory predicted the existence of a finite probability for an electron to tunnel through the potential barrier, when the applied field is high. Cold-cathode electron emissions are thus possible, under these conditions, at practically Fermi energy levels, as the high field would catalyze the tunnelling through the potential barrier by narrowing the barrier width for the Fermi energy electrons. The exact localization of the emission would then depend on the randomized fluctuations of high fields at the cathode, which were produced by positive space charges sweeping in proximity to it. For most purposes, this theory has been the working hypothesis of the last 60 years of field emission studies, which have centered upon the VAD mechanism, despite the fact that observed field gradients are evidently inadequate to explain breakdown as a function of the theoretical high field mechanism. The Fowler-Nordheim theory has therefore suffered major revisions and additions, mostly to account for the fact that it postulates, as a condition for cold-cathode field emission in large area electrodes, the presence of enormous fields ($>10^9$ V/m) and extremely low work functions, neither of which are borne out by experimental VAD investigations. Some researchers have found that the breakdown responsible for the VAD field emission is promoted by Joule heating and vaporization of microscopic emitter tips, and that this requires a critical current density (10^{12} A/cm^2), while others emphasized that this explanation and these thresholds did not hold for large area emitters and that a space charge effect of concentrating the ion distribution near the cathode promoted breakdown under these circumstances, when the field reached a critical value; large field enhancement factors (>1000-fold) have been postulated to explain the discrepancy between theoretical predictions and experimental findings regarding the critical breakdown field values, and others have demonstrated how this critical field value effectively varies with work-function and electrode conditioning.

The PAGD regime and its self-extinguishing autoelectronic emission mechanism stands as an exception to the high field emission theory as it currently stands with all its modifications, especially given that in this phenomenon we are confronted.. with a cathode emission that spontaneously occurs across the large gaps in large plate area pulse generators, at very low field values (down to $<1*10^4$ V/m), as shown above and in the '863 application. Moreover, a Fowler-Nordheim plot (in the form $\text{Log}_{10}(I/V^2)$ vs $1/V$) of the PAGD volt-ampere characteristic exhibits a positive slope, rather than the Fowler-Nordheim negative slope characteristic of VAD field emission. However, current density values obtained from correlations of autographic analysis of the cathode with an analysis of event-oscillogram (peak pulse currents), indicate that the PAGD current density J may reach values of 10^5 to 10^7 A/m^2 during the emission process (the larger Alzak craters have an associated lower J value), values which, at the upper end, do not reach the 10^9 A/m^2 current density threshold required by the Fowler-Nordheim theory. Considering these two distinct observations with regards to field strength and current density, we have to admit the existence of a low field, large area cold-cathode auto-electronic emission endowed with high current densities, which is not predicted by current field emission theory.

Unlike the typical VAD regime, the PAGD is neither a high frequency oscillation, nor does it occur in a random fashion. It constitutes a semi-regular, quasi-coherent, periodic energy transduction which cycles between cathode drop limits that are higher by a factor of 2–15 than typical vacuum arc cathode drops. The intermittent cathode emission responsible for the low frequency, pulsed behaviour of the abnormal glow, is also self extinguishing and self-starting, under the conditions we have defined. Furthermore, we have also identified a novel and unexpected dependency of the periodic pulse rate upon the cathode area. This indicates the presence of field emission control parameters heretofore unsuspected. It is likely that field fluctuations of the polarized pre-breakdown field is responsible for eliciting the particular localizations of the auto-electronic emission foci, as well as what imparts, in a lens-like fashion, the distorted field energy needed for electron surface release. In this sense, external, electrical or magnetic field fluctuations (e.g. motion of static charges or of constant magnetic fields) induced by us at pre-breakdown potentials, provoked PAGD emissions and breakdown at these levels.

In general, VAD studies have shown that, for large area electrodes, microgeometry, adsorbed gas layers and gas impurity contents of the cathode play a role in modulating field emission. In our PAGD studies, the interactions at the cathode surface and across the cathode potential drop are clearly modulated by: (1) the nature of residual gases, as shown by our air vs Argon studies; (2) their pressure, (3) electrode conditioning, (4) work-function and (5) cumulative pulse count, amongst others.

The plasma, in leak-controlled or low pressure PAGD devices, has both residual gas and metallic vapor substrates. In devices initially closed at high to very high vacua (diffusion pump pressures), the major residual substrate, whose presence increases with time of operation, is the metallic vapor released from the cathode and not impacted onto the envelope walls or the anode. It has been previously shown for externally (magnetically or electrostatically) pulsed plasma accelerators, that the amount of residual gas or vapor left in the interelectrode space diminishes with increasing number of consecutive discharges and a growing amount of electrode-insulator absorption of gas. The effect of such removal of residual gas or vapor is to decrease the vacuum of a sealed envelope. With high vacuum sealed PAGD generators we have observed that prolonged operation and sputter-induced mirroring of the envelope causes a progressive disappearance of the discharge, as the voltage potential needed to trigger it also increases. At the thermocouple, low frequency pulsed abnormal glow discharges can also be seen to increase the vacuum significantly. These results suggest instead the presence of a pumping mechanism in the PAGD which is somewhat analogous to that of sputter ion pumps, where collision of ionized gas molecules with the cathode is responsible for the sputtering of cathode material that either combines with the gas substrate ('gettering' action) or 'plasters over' the inert gas molecules onto the anode (a process known as 'ion burial'). These are the two basic pressure reducing actions of sputtered getter atoms, in ion pumps. However, in ion sputter pumps, the initiation of the cycle is a function of the presence of high velocity electrons in the high field plasma of the glow discharge, which are necessary to ionize the gas substrate molecules; also, the getter material typically has a high work-function for field emission. Hence, the sputtering is due to the secondary impact of plasma positive ions at the cathode, after plasma ionization has occurred in the interelectrode space. Altogether different is the mechanism of spontaneous, primary electron emission from the cathode, which is characteristic of the low field PAGD: here, the sputtering is caused by the electronic emission itself and attendant metallic vaporization processes. By artificially confining the firing foci to a part of the cathode, we have shown in the single diode configuration how the PAGD induced sputtering is associated with the cathode autoelectronic emission mechanism, rather than with the abnormal cathode glow per se, given the localization of sputtering onto the emission region of the plate, despite its overall cathode glow saturation.

These observations would thus seem to corroborate the hypothesis of a progressive vacuum increase with the cumulative number of emitted pulses, were it not for the fact that experiments performed with leak controlled devices (reported here and in previous studies) show that, when the negative pressure is maintained by balanced leak admission of air or argon, pulse rates still decrease with cumulative pulse count, and do so neither as a function of an increase in vacuum, nor as a function of envelope mirroring (unless this is so extensive as to establish envelope conduction), but rather as a function of processes (generally referred to as conditioning) inherent to the electrodes, specifically, to the cathode. We have further shown that, for such altered emitter states, the pressure of the vessel must be increased, not because of an increasing vacuum (precluded by the controlled gas leak), but because of the effect that residual gases may have in modulating the low field PAGD emission.

PAGD electrode conditioning is a cathode-dominant process resulting from the cumulative emission of high numbers of pulses by a cathode, and has been shown to be a factor independent of the nature and pressure of the residual gas and partially reversible only by operation with reversed plate polarity, unlike reports of copper cathode-dominant conditioning. It is thought that electrode conditioning and the accompanying increase in VAD breakdown potential are due to the progressive adsorption of residual gases, though cathode-dominant conditioning processes, such as subjecting the vacuum gap to consecutive discharges, have been shown to correlate the decrease in plasma impulse strength with electrode outgassing of absorbed or adsorbed gases. Moreover, given the pitting action of crater formation at the cathode by the PAGD regime, and, as we shall see below, the metallic plating of the anode, the PAGD cathode-dominant process of conditioning we have observed with respect to decreased pulse frequency and increase in potential, suggests that the apparent increase in cathode work function is not due to gas adsorption or absorption. These processes are more likely to occur on the plated anode. It is likely that, given the observed PAGD pressure reducing effect caused by the cathodic jet, a certain outgassing of the cathode is in fact occurring during PAGD function. One might also expect that the anode, if plated by sputtering atoms, would increase its gas content in the formed surface film. However, controlled leak experiments suggest instead that some other type of alteration of the cathode work function is occurring, which is, as we shall examine below, independent of the adsorbed gas state of the electrodes, as well as independent of the PAGD ion pump-like effect. Nonetheless, even at the level of the anode, the PAGD sputtering action may have contradictory effects: it may impact interelectrode gap molecules onto the collector, as well as release, by ionic bombardment and vaporization, gases adsorbed to, or contaminating the anode. If we assume that gas adsorption by impact on the collector is the predominant mechanism, one could explain the increase in the number of breakdown sites per unit time, as observed by us for a re-reversed cathode, if the number of PAGD breakdown sites depended on the quantity of adsorbed gases, eg oxygen, on the cathode being tested. Recovery of the cathode work-function would depend on the electronic charge recovery of the positively charged, adsorbed or occluded gas layer at the cathode- either by reversal or as a function of time of inactivity. The surface film theory of 'electrical double layer formation at the cathode' in fact contended that, low field flash over is a photocathodic effect dependent upon the presence of a glowingly positively polarized gaseous film at the cathode; this film would lower the cathode emissivity by decreasing the field between the cathode surface and the leading edge of the cathode glow, across the cathode drop. However, even though the surface film theory of 'electrical double layer formation at the cathode' predicts the lowering of the emission breakdown potential and the increase in flash over rate when the electrodes are reversed—as the anode would have acquired a surface charge capable of affecting the breakdown potential, it acknowledges nevertheless, that the anodic surface charge hardly explains the observed intensity of the polarization effects. Moreover non-reversed, conditioned cathodes retained their lower PAGD frequencies in a time independent manner, for as long as reversal was avoided (excluding a PAGD frequency recovery effect due to plate cooling, which may be as short as 15 minutes). PAGD conditioning was independent of idle time and increased with cumulative pulse count. Moreover, the AGD pulses are not UV photocathodic Townsend discharges, liberating secondary electrons via positive ion impact at the cathode. Nor could photocathodic emissions generate currents of the magnitude observed in the PAGD. Lastly, the PAGD discharge and breakdown thresholds appear to be unaffected by UV, though they may be somewhat depressed by visible light, and the emission mechanism in the PAGD is the primary process.

Removal or flattening of protuberances and tips from the emitting cathode by the action of the discharge, is a process also thought to play a role in hardening the cathode or increasing its field emission work-function. However, this explanation may not be adequate for the PAGD emission process, if we consider our metallographic findings of a smoothing action of the discharge at the collector. In fact, it would appear that the flattened, smoother, plated, mirrored and cleaner surfaces subjected to PAGD bombardment are the explanation for the observed increased emission ability of re-reversed cathodes: mirrored Alzak surfaces emit at higher frequencies than do dull H34 and H220 surfaces; new, polished surfaces emit at a higher frequency than do pitted, broken in surfaces; anode surfaces, never before utilized as cathodes but subjected to prolonged PAGD action, emit at higher frequencies when employed as cathodes, than do new, identical cathode surfaces; and ex-cathodes, employed for prolonged periods as anodes, regain a higher emission frequency upon re-use as cathodes. The better PAGD emission performance of smoother cathodes, compared with the worse VAD emission performance of the same, when pitted cathodes (lacking protuberances) are used, requires explanation.

Rakhovsky has put forth a VAD model for cathode spots, that distinguishes between Type I spots (quickly moving spots, far from steady state and responsible for crater formation), and Type II spots (quasi-stationary and near steady-state, but leaving an itinerant track with no sign of crater formation). Whereas the former would obey the Fowler-Nordheim requirement for high fields ($>10^9$ V/m), the latter could hardly be expected to do so with typical arc voltage drops in the order of 10 V. Once again, autographic analysis of the PAGD emission aspect indicates mixed characteristics: the PAGD cathode spot is a hybrid. It behaves as an intermittent instability that leaves single (e.g. in H34) or clustered (e.g. in Alzak) craters, which are both qualities of Type I cathode spots; and it exists under low field conditions ($<10^5$ V/m), with cathode drops of 20 to 150 V, in a quasi-coherent mode, leaving an itinerant track of successive craters when operating at the higher frequencies, all of which are properties approaching those of a VAD Type II cathode spot. Furthermore, the macroscopically visible metal sputtering (due to the explosive action of the PAGD emission phenomenon) occurring at the upper end of the permissible DC current input scale, and the presence of large solidified molten metal droplets in and around the craters, suggest models which have been proposed for explosive electronic emission. Explosion models propose that the creation of a residual plasma ball in front of a microprotuberance provokes the large potential drop at the prospective emission focus and sufficiently high resistive and Nottingham heating to reach $>10^7$ A/cm^2 current densities during the explosive consumption of these microemitters. Whether the explosive action associated with cathode spots is an auxiliary effect that applies solely to the vaporization of the emitting microprotrusion, or an integral emission and vaporization explosive process, it does not appear that it can be restricted to high-field VAD Type II cathode spots, given that it can be equally made to occur with the low field PAGD hybrid cathode spot, and be macroscopically observed. Indeed, in the plate diode configuration, it is easy to visualize the metallic particle explosions that surround and accompany the plasma jets, near to upper current limit conditions. However, if we are to assume that any of these models apply to the emission mechanism, we would, in all likelihood, have to conclude that the PAGD initial emission sites must be submicroscopic (100 to 10 nm), rather than microscopic. Resolution limits to our own metallographic examination of the smoothing action of the PAGD discharge on the collector would thus have precluded us from detecting formation of such submicroscopic protrusions, as well as their presence in a 'soft' cathode- and thus infer their disappearance from a pitted, hardened cathode; but if the disappearance of such submicroprotuberances were responsible for the observed alteration of cathode work function, one would also thereby have to postulate the existence of a mechanism for microroughness regeneration (eg. tip growth) at the anode, in order to explain the observed increased emission upon cathode re-reversal. Furthermore, this regeneration would have to be actively promoted by operation with reversed polarity, and this is problematic. Focusing of the distorted or magnified field upon alumina inclusions on pure iron electrodes has been demonstrated to degrade breakdown voltage for field emission, but the effect was greater for larger microscopic particles. If we were to apply this concept to our work, it would require the existence of unmistakably abundant microscopic heterogeneities in the quasi-homogeneous electrode surfaces employed, which we did not observe; on the contrary, their absence suggests that either the microroughness responsible for the low field PAGD emission is submicroscopic, or that the field distortion responsible for eliciting the PAGD is independent of the presence of these protuberances. This last possibility must be taken all the more seriously, in light of the fact that PAGD functioning is able to cover with craters the entire surface of an emitter.

Whereas the discharge potentials observed in the PAGD have been shown to be relatively independent of the kind of gas present, there is a gas effect in the PAGD phenomenon, particularly in what concerns its frequency, observed when the same 'run down' cathode was capable of much higher emission rates when exposed to argon, than to air. Utilizing the technique of bias sputtering, it has been demonstrated that the number of charge symmetric collisions (dependent upon sheath thickness d and the ion mean free path) in the plasma sheath, which are responsible for lower energy secondary peaks in ion energy distribution N(E), at pressures of 0.2 Torr, is substantially greater in argon than in argon-nitrogen mixtures, and thus that, under these conditions, mostly Ar^+ and Ar^{++} ions impact the negatively biased electrode. In non-equilibrium RF discharges, greater ion densities have also been attained with argon, than with air. With respect to field emissions, one would expect a gas effect only with regards to changes on surface conditions, though such studies have shown contradictory effects of argon upon cathode work function. In light of the foregoing, and given that the PAGD is an emission discharge and not a sputtering discharge per se, in the strict sense, we can conceive of the role of inert gas atoms in increasing, as compared to air or nitrogen, the ion energy density distribution at the PAGD cathode spot interface with the cathode surface emitter, and thus elicit increased emission rates from the cathode, by pulling electrons from the metal via the field effect. While this is consistent with the concept of focused distortions of space-charge field fluctuations inducing localization of the emission foci, the argon effect can be observed in the PAGD regime over the entire range of the Paschen low vacuum curve, and into Cooke's mid to high vacuum curve, at low fields and without negative biasing. Thus, it is not simply a high pressure (nor a gas conditioning) effect, even if the gas effect in question applies to the description of a local pressure rise at the emission site/cathode spot interface, which may play a role in enhancing the local field.

Considered together, the PAGD emission-derived sputtering, the observed metallic plating of the anode and the explosive aspect of the discharge, suggest the presence of a jet of metallic vapor present in the discharge and running, contrary to the normal flow of positive ions, from the cathode to the anode. This jet appears to have properties similar to the high speed vapor ejected from the cathode in a VAD, as first detected by Tanberg with his field emission pendulum (Tanberg, R. (1930), "On the cathode of an arc drawn in vacuum", Phys. Rev., 35:1080) In fact, the VAD high field emission process is known to release, from the cathode spot, neutral atoms with energies much greater than the thermal energy of the emission discharge. This anomalous phenomenon brings into play the role of the reported cathode reaction forces detected in vacuum arc discharges (Tanberg, as above, also Kobel, E. (1930), "Pressure and high vapour jets at the cathodes of a mercury vacuum arc", Phys. Rev., 36:1636), which were thought to be due to the counterflow of neutral metallic atoms, from the cathode onto the anode (charged metallic ions are normally expected to target the cathode). In absolute units of current, this current quadrature phenomenon has been shown to reach, in the VAD regime, proportions of the order of $100*I^2$ (see also the Aspden papers referenced below). Early interpretations attributed this to the cathode rebounding of <2% of gas substrate-derived plasma positive ions hitting the cathode and being charge neutralized in the process, but having kept most of their thermal energy. Tanberg held instead that the counterflow of neutral particles responsible for the cathode reaction force was cathode derived, effectively, that it constituted a longitudinal interaction acting in the direction of the metallic arc jet. However, even though secondary high energy distributions of neutral atoms emanating from the cathode do not have thermal energies, their modal distribution does (Davis, W. D. and Miller, H. C. (1969) J. Appl. Phys., 40:2212) furthermore, the major anomalous atomic counterflow that accompanies the high energy electron flow toward the anode, was shown mass spectrographically to consist predominantly of multiply ionized, positively charged ions of cathode metal, rather than neutral atoms. If this made it easier to abandon the primacy of the rebounding model, it was now more difficult for field emission theorists to accept and explain the observed high energies (ion voltages in excess of the discharge voltage drops) and the high ionization multiplicity associated with these counterflowing positive ions. This field of investigation has indeed been one of the mounting sources of evidence suggesting that there is something amiss in the present laws of electrodynamics. The anomalous acceleration of counterflowing ions, and the energy transfer mechanisms between high speed or 'relativistic' electrons and ions in a plasma (Sethion, J. D. et al, "Anomalous Electron-Ion Energy Transfer in a Relativistic-Electron-Beam-Heated Plasma" Phys. Rev. Letters, Vol. 40, No. 7, pages 451–454), in these and other experiments, has been brilliantly addressed by the theory of the British physicist and mathematician, H. Aspden, who first proposed a novel formulation of the general law of electrodynamics capable of accounting for the effect of the mass ratio factor (M/m') in the parallel (and reverse) motion of charges with different masses, (Aspden, H. (1969) "The law of electrodynamics", J. Franklin Inst., 287:179; Aspden, H (1980) "Physics Unified", Sabberton Publications, Southampton, England). The anomalous forces acting on the counterflowing metallic ions would stem from their out of balance interaction with the emitted high speed electrons, as predicated by the electrodynamic importance of their mass differential. This results in a fundamental asymmetry of the plasma flow between electrodes, localized onto the discontinuous interfaces of the plasma with the electrodes, namely, in the cathode dark space and in the anodic sheath: on the cathode side, electrons act upon ions, as the emitted electrons having less than zero initial velocities, drift against the incoming ion flux and in parallel with the ion and neutral counterflows; on the anode side of the discharge, positive ions flowing toward the cathode confront mainly the incoming counterflow of positive ions and neutral atoms, as the high speed electrons have abnormally transferred their energy to counterflowing, high speed, cathodic metal ions. An out of balance reaction force thus results at the cathode, to which the leaving metallic atoms impart a force of equal momentum but opposite direction, a force which is added to the cathode momentum generated by impacting, normal flowing positive ions. Moreover, Aspden confirmed theoretically the fundamental contention of Tanberg's experimental findings that an electrodynamic force will manifest itself along the direction of the discharge current flow, and thus, that the atomic counterflow is a metallic jet. Aspden further demonstrated that this asymmetry of plasma discharges does not imply any violation of the principles of conservation of energy and charge equivalence, given that there will be no out-of-balance force when such anomalous forces are considered in the context of the whole system of charge which must, perforce, include the local electromagnetic frame itself. Such discharges must be viewed as open energy systems, in balance with their electromagnetic environment: their apparatuses may constitute materially closed or limited systems, but they are physically and energetically open systems. Current work on Aspden's formulation of Ampere's Law indicates that both classical electromagnetism and special relativity ignore precisely, in circuits or in plasma, the longitudinal interactions that coexist with transverse ones. Standing longitudinal pressure waves, of a non-electromagnetic nature, have been previously shown in plasma electrons, which did not conform to the Bohm and Gross plasma oscillation mechanism (Pappas, P. T. (1983) "The original Ampere force and Bio-Savart and Lorentz forces", Il Nuovo Cimento, 76B:189; Looney, D. H. and Brown, S. C. (1954) "The excitation of plasma oscillations" Phys. Rev. 93:965)

The present theoretical approach to the novel regime of electrical discharge which we have isolated in specially designed devices, and to its mixed glow-arc characteristics, suggests that a similar, out-of balance current quadrature phenomenon occurs in the discharge plasma during the low field, autoelectronic emission-triggered PAGD, and is responsible for the observed surplus of energy in the experimental system described in this report. Clearly, all the evidence we have adduced indicates that there is a powerful longitudinal component to the emission-triggered PAGD, ie that the discharge pulses characteristic of this pre-VAD regime are longitudinally propelled jets of cathode-ejected high speed electrons and high speed ions. We have performed experiments, in the PAGD regime of operation, with very thin axial members that bend easily when placed in the path of the discharge, or with Crooke radiometer-type paddle-wheels, and both show the presence of a net longitudinal force in the plasma discharge acting in the direction of the anode, which confirms the magnitude of the atomic counterflow (ionized and neutral) present during the PAGD, very much like Tanberg's pendulum did for the VAD. These observations also tally with the explosive action of the emission mechanism, such as we have examined it above. In this context, two aspects of the PAGD are remarkable: the fact that a phenomenon akin to field emission occurs at low field values, for large area electrodes across large gaps, and the conclusion that the PAGD must deploy an excessively large counterflow of, in all probability, both ionized and neutral cathodic particles. The observation of ion current contributions to the cathode current on the order of 8 to 10%, in VADs, can hardly apply to the PAGD mechanism responsible for the anomalous currents and counterflows observed. Hence, we should further expect that the characteristically intermittent, or chopped current regime of the PAGD, is a major factor in the generation of disproportionately high energy longitudinal pulses and in allowing our system to capture most of the electrical energy output from the device. In all probability, field collapse at the end of discharge favours the nearly integral collection of the plasma charge, and ensures the transduction of most of the plasma energy of the pulse (blocked, as it is, from flowing back through the input port to the drive pack) to the output port, through the parallel, asymmetric capacitance bridge that interfaces with the charge recovery reservoir (the charge pack). Collapse of the field of the discharge may also be a contributing factor to the anomalous acceleration of ions, and to the observed anode plating effect. It is equally possible that such abnormally large longitudinal pulses may never be observable, for a given arrangement and scale, above threshold frequencies of the oscillation; we have, in this sense, presented data that indicates that for a given geometry, above specific PAGD frequencies, the capture of surplus energy decreases steadily in efficiency until it ceases altogether, for a given arrangement. The point at which this surplus begins to decrease coincides with the setting in of frequency-dependent irregularities in the discharge sequence and, most importantly, it coincides with a reduction of the peak pulse current for each PAGD pulse. We have further remarked that increasing the PAGD frequency above the zero surplus point, for a given arrangement, by manipulating any of the frequency control parameters, provokes the slippage of the PAGD into a full fledged VAD regime, while input currents greatly increase and output peak currents greatly decrease (to comparable peak input levels of 10 to 15A). The transition between the two modes of emission-triggered discharge, PAGD and VAD, thus appears to be tied in to adjustable thresholds in the frequency of the emission discontinuities; in this sense, it is rather likely that the plasma field collapse plays a major role in regularizing and optimizing the anomalous energies of field emissions, as in the PAGD regime. At low frequencies of low field emission, the emission regime is highly discontinuous, diachronic and regular, for it has time to fully extinguish the discharge; hence the PAGD singularity, in which the phases of each discharge pulse are well defined and sequential. Above a given high frequency, when ion and electron recombination will happen more often, before each can be collected at the electrodes, the stream of emitted discontinuities merges into a noisy, randomized continuum, where simultaneous emissions become possible and the plasma field no longer has time to collapse and fully resolve the longitudinal pulses. Any anomalous energy generated is then minimized and trapped in the plasma body and, in these conditions, the VAD regime eventually sets in. Such model would easily explain why the high field VAD experiments performed to date have never detected such extraordinarily large anomalous forces.

On the other hand, the quasi-coherent aspect of the discharge suggests that the vacuum gap, in functioning during the PAGD regime both as an insulator and as a conductor with capacitative and self-inductive properties, is periodically altered by large and intense polarizations which are resolved by the discrete emission of longitudinal pulses from the cathode. It is possible that these nonlinear oscillations resulting from sudden depolarization of the vacuum gap by high speed explosive emissions elicited at the convection focus of the distorted field, might be in resonance or near resonance with the external circuitry, but the most apparent effect of increasing the capacitance in all bridge members is to increase the jet current and the transduced current flowing into the charge pack. The PAGD amplitude variation also presents, after the large negative discontinuity, a growing oscillation at very high resonant frequencies, which are typical of inductive chopping currents in a VAD, before extinction occurs. Unlike the VAD inductive case, in the absence of any coils other than the wire wound resistors, the PAGD relaxation oscillations which follow each pulse only extinguish the discharge when the voltage potential of the amplitude curve rises above the applied voltage, just as the plasma potential drops the most. Given the entirely non-inductive nature of the external circuit utilized in many instances, the inductive properties in evidence are those of the vacuum device itself. It also suggests that, in the absence of any need of an applied external magnetic field for the PAGD discharge to occur coherently, it is possible that the magnitude of the currents generated produces by itself a significant self-magnetic field. Thus, we cannot rule out the possibility of a self-organization of the plasma discharge, which may, in Prigogine's sense, constitute a dissipative structure (Prigogine, I. and George, C. (1977), "New quantization rules for dissipative systems", Int. J. Quantum Chem., 12 (Suppl.1):177). Such self-ordering of the PAGD plasma jet is suggested by the experimentally observed transition of these pulses from the current saturated limit of the normal glow discharge region, into the PAGD regime, as a function of increasing current: smaller foci of discharge can be seen to discontinuously agglutinate into larger emission cones, or into jets with a vortex-like appearance, when the input current reaches a given threshold. It is possible that, under these conditions, the distribution of the charge carriers and their sudden fluctuations may render any steady state plasma boundary conditions ineffective and provoke a singularity in the discharge mechanism; this nonlinear behaviour, together with any self-magnetic effects, might provide radial coherence of the plasma flow along the longitudinal path of the discharge. This concept is akin to what has been proposed for periodically evanescent solution structures referred to as instantons, that represent self-organizing transitions between the two states of a system. The PAGD may well be an instance of an instanton type structure bridging the open, or conductive, and the closed, or insulating, states of the vacuum gap. An analytical formulation of the problem of the plasma flow from the cathode spot to the anode, which would take into account the self-magnetic and self-organizing properties of the PAGD plasma channel, would be extremely difficult, given the out of balance longitudinal force, its abnormal energy transfer and associated counterflow, as well as the competition between collisional and inertial exchanges.

The plating observed at the anode most likely results from the impact of counterflowing ions (and possibly neutral atoms), whereas the pitting of the (locally molten) cathode results from the emission of vaporized metallic material and electrons, as well as, secondarily, from bombardment by incident positive ions. The first action smooths the surface by mirroring it (deposition of cathode-derived atoms) and abrading it, whereas the latter smooths it in places by rounding concavities and by forming molten droplets upon local cooling, while simultaneously roughening it on the crater peripheries. One might think that this cathode roughening should lower the work function and facilitate the discharge, but the facts indicate that just the opposite must be happening in view of changes in the PAGD according to the nature and state of the cathode surface. The observed alterations of electrode work function for PAGD low field emission must thus be related to the molecular and charge effects of these different actions at the two electrodes. It appears that for large parallel plate electrodes, the PAGD low field emission is modulated by the nature and, most likely, by the molecular structure of the metallic surface layer of the emitter.

We have thus devised a system for the capture as electricity of the energy of anomalously energetic longitudinal pulses sequentially triggered by spontaneous emissions of high speed electrons and ions generated from low work function cathodes, during the low field and singularly mixed PAGD regime of electrical discharge in vacuo. To confirm the above interpretation of the anomalous flux in the observed PAGD phenomenon, the cathode jet composition, as well as time- and usage-dependent changes occurring in the tubes, with diverse sealed negative pressures and after submission to prolonged PAGD operation, must be analyzed mass spectroscopically. In any event, the excess energy present in the anomalous counterflowing force appears to stem from a discharge mechanism that effectively pulls high speed electrons and constituent atoms out of a metal surface, at low fields and with high current densities, and is modulated by a complex multiplicity of parameters. The system described appears to transduce efficiently the observed nonlinear longitudinal pulse discontinuities of the plasma field, under conditions of current saturation of the cathode, because the self-extinguishing and self-limiting properties of the discharge allows the energy from the collapse of the discharge to be captured. The particular design of the circuitry, which couples a rectification bridge to the asymmetric bridge quadrature of large capacitances, placed at the output of the PAGD generator, permits effective capture. Our findings constitute striking evidence for Aspden's contention of a need to revise our present electrodynamic concepts. The dual ported PAGD discharge tube circuits which we have described are the first electrical systems we know of which permit effective exploitation of anomalous cathode reaction forces and allow for the recovery of electrical energy from systems exhibiting this effect. Any apparent imbalance in the electrical energy input to the system and withdrawn from the system by its operator must be considered in the context of the entire continuum in which the system operates, within which it is anticipated that accepted principles of energy balance will be maintained.

Moreover, the energy conversion system of the invention has substantial utility as an electrical inverter accepting direct current, and providing one or more of a direct current output at lower voltage and higher current, variable frequency input to alternating current motors, and, by suitable combinations of discharge tube systems, more flexible DC to DC conversion systems.

As an alternative to the batteries used in the experiments described, a DC power supply may be utilized or, more advantageously from the viewpoint of entailing less transformation losses, a DC generator to provide the electrical energy input to the system. As a DC motor can be run directly from the rectified output of the circuit of FIG. 9 at El–E2, in place of a battery charge pack, DC motor/generator sets of suitable characteristics (in terms of back E.M.F. and circuit loading) can be used to charge the batteries of the drive pack, utilizing the rectified PAGD output to drive the DC motor component of the set. This provides a simple, one battery pack solution, where the PAGD input and output circuits are electrically separated by the DC motor/generator interface: the drive pack is simultaneously being discharged to drive PAGD production, and charged by the DC generator output which, in turn, is being driven by the electromechanical transformation of the rectified PAGD output that would typically accrue to a charge pack in the experiments already described. The main limitations to such an arrangement lie in the efficiency of the motor and generator transformations utilized.

A pulsed DC source could be used to provide input to the circuit if suitably synchronized, but care is needed not to interfere unduly with the autoelectronic mechanism of the field induced cathode emissions.

TABLE 1

Results for the ballast resistance (and current) dependent PAGD frequency utilizing an H34 aluminum pulse generator with 128 cm^2 plates at 5.5 cm distance, in the triode configuration, at a pressure of 0.8 Torr. The circuit employed is that of the present invention, as described in the third Results Section. DCV = 560.

We claim:

1. Apparatus comprising a discharge tube and an electrical circuit containing said discharge tube and configured to operate the latter to provide endogenous pulsatory cold cathode autoelectronic emissions, the circuit being double ported with an input port connected to a source of direct current at a potential sufficient to initiate said emissions, and an output port connected to a current sink effective to absorb at least a substantial portion of electrical energy released by collapse of said emissions.

2. Apparatus according to claim **1** configured so that the emissions occur in a pulsed abnormal glow discharge regime.

3. Apparatus according to claim **2**, wherein the input port includes components ensuring that the flow of current therein is unidirectional, and incorporating impedance sufficient to limit the flow of current therein.

4. Apparatus according to claim **2**, including capacitors connected to the discharge tube, the input port and the output port, which provide charge storage in the input port and direct current isolation between the input and output ports.

5. Apparatus according to claim **4**, wherein the output port comprises a rectifier having an input connected to said capacitors, reservoir capacitance connected to the output of said rectifier, and reverse current blocking devices connected between said reservoir capacitance and the current sink.

6. Apparatus according to claim **5**, wherein the rectifier is a bridge rectifier, and the reservoir capacitance is provided by a capacitor bridge having ends connected to outputs of the bridge rectifier, and an intermediate point connected to one input of the bridge rectifier.

7. Apparatus according to claim **4**, further including an alternating current motor and a capacitor in series, connected between the connections of said capacitors to the output port.

8. Apparatus according to claim **2**, wherein the current sink comprises a secondary battery.

9. Apparatus according to claim **2**, wherein the current sink comprises an electric motor.

10. Apparatus according to claim **2**, wherein the direct current source comprises a secondary battery.

11. Apparatus according to claim **2**, wherein the direct current source is a DC generator.

12. Apparatus according to claim **9**, wherein the motor is a DC motor.

13. Apparatus according to claim **10**, including a circuit for charging from the output port a battery to be used as the direct current source.

14. Apparatus according to claim **2**, wherein the direct current source is a rectified AC source.

15. Apparatus according to claim **2**, wherein the discharge tube is connected as a single diode.

16. Apparatus according to claim **2**, wherein the discharge tube is connected as a multiple diode with plates connected as cathodes and an intermediate electrode connected as an anode.

17. Apparatus according to claim **2**, wherein the discharge tube is connected as a triode, with an intermediate electrode functioning as an auxiliary cathode.

18. Apparatus according to claim **2**, wherein a first potential is applied to the input port by the source of direct current to induce emission, a back EMF is applied to the output port by the current sink, and an extinction potential of the emissions is greater than the back EMF.

19. A method of energy conversion, comprising initiating plasma eruptions from the cathode of a discharge tube operating in a pulsed abnormal glow discharge regime utilizing electrical energy from a source in a first circuit connected to said discharge tube, and capturing electrical energy generated by the collapse of such eruptions in a second circuit connected to said discharge tube.

20. A method according to claim **19**, wherein current flowing into the discharge tube during said eruptions is at least 50 ma.

21. A method according to claim **19**, wherein current flowing into the discharge tube during said eruptions is at least 500 ma.

22. A method according to claim **19**, in which charge carriers within plasma outputs are accelerated through at least one of an electric and magnetic field.

23. A method of energy conversion, comprising inducing endogenous pulsatory low-field, large-area cold-cathode autoelectronic emissions from the cathode of a discharge tube capable of sustaining such emissions, utilizing electrical energy from a source in a first circuit connected to said discharge tube, and capturing electrical energy generated by the collapse of such emissions in a second circuit connected to said discharge tube.

[57] **ABSTRACT**

A Satellite Weather Modification System (SWMS) uses earth satellites to harness solar energy to modify the thermodynamics and composition of the earth's atmosphere. SWMS has three subsystems: The first subsystem includes a network of earth satellites called Satellite Engines (SEs) used to reflect solar energy and/or transform solar energy into other forms of energy beams discharged at specified locations. The media at these locations and the media through which the energy beams pass absorb these energies and change them into heat. The second subsystem includes a large network of Remote Sensing Devices (RSDs). These sensors are used to measure local media compositions, dynamic parameters and thermodynamic properties. Sensor measurements are fed back to the third subsystem, which includes a network of Ground Control Stations (GCSs). GCSs provide energy beam guidance by estimating each beam's characteristics and its aim point trajectory as functions of time. Integration of these three subsystems establishes a sensor feedback energy beam guidance and control loop. SWMS's weather modification applications include alteration of precipitation, reclaiming of wasteland, reducing damage by bad weather, and improving environment. Its non-weather related applications include supplying concentrated energy to electricity generating stations (solar, wind and hydro), high latitude greenhouse farms, and solar powered airplanes.

FIG. 7

WEATHER MODIFICATION BY ARTIFICIAL SATELLITES

This is a divisional of prior application Ser. No. 08/480,883 filed Jun. 7, 1995, now U.S. Pat. No. 5,762,298, which is a continuation of prior application Ser. No. 07/675,880 filed Mar. 27, 1991, now abandoned.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to solar-based weather modification and energy transfer in such a manner as to improve people's living standards by reducing their energy cost and food cost and simultaneously improving the environment.

2. Description of the Prior Art

Art prior to the present application includes the following:

U.S. Pat. No. 4,402,480

Title: Atmosphere Modification Satellite

Inventor: D. M. Udell, Sep. 6, 1983

U.S. Pat. No. 3,613,992

Title: Weather Modification Method

Inventor: R. J. Knollenberg, Oct. 19, 1971

U.S. Pat. No. 4,371,135

Title: Solar Array Spacecraft Reflector

Inventor: J. E. Keigler, Feb. 1, 1983

U.S. Pat. No. 4,305,555

Title: Solar Energy System with Relay Satellite

Inventor: C. E. Davis, Dec. 15, 1981

In addition, the following publications are of interest:

Astronautical Guidance

by R. H. Battin, McGraw-Hill Book Co. 1964

Introduction to Radar Systems

by M. I. Skolnik, McGraw-Hill Book Co. 1962

and

Radar and the Atmosphere

by A. J. Bogush, Jr., Artech House 1989.

In contrast to much of the prior art, this invention employs only solar energy, earth satellites, remote sensing devices and ground control computers. No dispensing of chemicals is needed. The Satellite Weather Modification System (SWMS) is a local as well as a global weather modification tool. For example, SWMS can simultaneously bring rain to dry regions in southern California and drought regions in southern Ethiopia within in a few orbital periods of the Satellite Engines. Most remarkable of all is that these and many other tasks can all be accomplished by switching between some computer codes.

This invention is based on the realization that natural weather patterns always leave opportunities to permit regional weather modifications which are within the capabilities of the proposed Satellite Weather Modification System (SWMS). A fully developed SWMS has the potential to provide the following benefits.

1. Modify cooling, warming, or precipitations of selected regions of earth, thus modifying local and/or global weather patterns.

2. Create and maintain grass or forest lands to balance the rise of carbon dioxide contained in the earth's atmosphere, thus reducing the threat of global warming.

3. Transform some wasteland into productive farmland.

4. Increase farm, fishery and forestry productions at higher latitudes.

5. Increase electricity production on land directly from concentrated solar energy.

6. Increase hydroelectricity production by inducing precipitation in regions upstream of hydroelectric dams.

7. Reduce home and industry energy cost.

8. Reduce environmental damage by harsh weather.

9. Reduce damage to the environment due to the use of fossil fuel and nuclear fuel.

10. Create a unique self-supporting business based on SWMS, which can provide both weather-related and non-weather related services.

SWMS can be implemented employing components which are currently available, including means for reflecting solar rays or discharging infrared radiation or laser beams or incandescent lights.

SWMS improvements can be augmented gradually, still using conventional components, to include discharging frequency agile and or intensity agile energy beams or pulse trains from Satellite Engines (SEs). Each frequency agile energy pulse is designed to penetrate a specified air mass layer of specified composition. For example, these energy pulses can be used to modify a specified air mass inside a thick cloud.

SUMMARY OF THE INVENTION

This invention is an aerospace system designed to harness solar energy to modify the earth's weather. This system is called Satellite Weather Modification System (SWMS). This invention disclosure covers three areas. A first area involves the design and/or integration of three SWMS key subsystems. A second area involves specifying basic SWMS weather modification techniques. A third area involves the design of unique SWMS applications into self supporting businesses.

The first area of this invention disclosure covers the three SWMS key subsystems. They are:

1. Satellite Engines (SEs)

The basic function of an SE is to reflect solar energy or to transform solar energy into another form of energy before discharging it to a specified location. Each SE is a specially designed earth satellite. In a mature SWMS, many millions of SEs will be operating in a coordinated manner. As a minimum capability, each SE will be designed to reflect solar energy and simultaneously convert solar energy into electricity via solar cells. Advanced SE models will be capable of transforming solar energy into energy beams of different frequencies before discharging them. These advanced SEs can simultaneously discharge solar energy, frequency agile and intensity agile MMW (millimeter wave) or RF or microwave pulse trains, infrared radiations, laser light and incandescent light as the mission may require. All physical characteristics of each energy beam (solar or otherwise) are adaptively estimated by Ground Control Stations (GCSs). GCS also estimates each energy beam's guidance by defining its desired aim point trajectory. The criteria used to select and to guide each energy beam are based on an estimated specific thermodynamic change taking place in a specific air mass that satisfies some required weather condition changes.

Each SE will have gimbals panels (i.e., panels mounted on gimbals) on its outer surfaces. Each gimbals panel has a reflector on one side and solar cells on the other side. Also, gimbals-mounted antennae and lamps are attached to the SE structure frame. The SE controls the direction of each energy beam by controlling each panel's two gimbals orientations with respect to the SE structure frame. By using flywheels (or other methods), each SE also controls its structure frame orientation with respect to inertial space.

A minimum SWMS configuration requires that all SEs be placed in two non-coplanar orbits. These orbits are slightly inclined with respect to each other. One orbit will always be higher than the other orbit. Each SE structure frame will maintain an average angular rate of one revolution per year with respect to inertial space. During each orbit around the earth an SE will experience two different operating modes, depending on whether the SE is inside or outside earth's shadow. These modes are described below:

When SEs are outside earth's shadow, SEs in the higher orbit will rotate their solar cell panels (on one SE side) facing the general direction of the sun. At the same time SEs will rotate their reflector panels (on the other side of the SE) facing away from the sun. SEs in the lower orbits will have their reflector panels (on one SE side) facing the general direction of the sun and their solar cell panels (on the other side of the SE) facing away from the sun. This arrangement allows the solar rays first reflecting from the lower orbit SEs' reflectors to the reflectors on the higher orbit SEs, before finally re-reflecting these solar rays to earth (in FIG. **3** see incoming solar rays **3***a*, rays **3***b* reflected from the lower orbit to the higher orbit, and rays **3***c* reflected from the higher orbit into the earth's atmosphere).

When SEs are inside earth's shadow, SEs will rotate their reflector panels to face the reflector panels in the other orbit. This arrangement allows the solar rays to travel between the two orbits inside earth's shadow before discharge to earth (see rays **3***z* in FIG. **3**).

2. Remote Sensing Devices (RSDs)

The basic functions of RSDs are to continuously measure the actual atmospheric conditions of each specified weather cell. Ideally, there will be billions of RSDs of every kind distributed over the globe. These RSDs are used to continuously monitor the actual thermodynamics, dynamics, compositions and other physical conditions of the atmosphere, land and water surfaces, subsurfaces, sun and Satellite Engines. There will be different kinds of RSDs measuring different parameters. Some RSDs will be stationary on earth. Other RSDs may be located on Solar Powered Satellite Airplanes (SPSAs), on balloons or on SEs. All RSD measurements are time and location tagged before transmitting to their respective local Ground Control Stations (GCSs) for data correlation and analysis. Some measurements are sent directly to or measured directly by SEs.

3. Ground Control Stations (GCSs)

The basic function of GCSs is to provide guidance to each SE. This includes defining the characteristic of each energy beam and its aim point trajectory as functions of time. Each GCS includes a network of supercomputers, special algorithms, mathematical models, monitors, control panels, data storage devices, electronic libraries, data transmitters and data receivers. The main tasks of each GCS are: To maintain detailed information about local weather conditions, to integrate raw local RDSs measurements with filtered information about weather conditions of other locations (received from other GCSs), to extrapolate weather conditions to future time points, to monitor assigned Satellite Engines' (SEs') status, to evaluate assigned SEs' performances, to identify potential local weather patterns which can be modified by SWMS, to estimate potential weather modification options, to evaluate desired weather condition requests, to select optimal SEs groupings, to estimate SEs weather modification tasks options, to coordinate all SEs tasks, to assign and transmit detailed weather modification tasks to each assigned SE (i.e., specify energy beam's characteristic and its aim point trajectory as functions of time), to maintain communication between GCSs, RSDs and SEs, and, finally, to accept human inputs and controls.

The second area of this invention disclosure involves specifying SWMS weather modification techniques. This includes: Cooling the earth by reflecting solar rays back into deep space, warming local regions by redirecting solar rays to local areas, creating clouds by warming local wet surfaces and modifying local air mass velocity components by controlled heating of specific air masses to create pressure differentials.

The third area of this invention disclosure involves organizing SWMS unique services into self supporting business ventures. The SWMS services include: Weather modifications (cooling, warming, altering precipitations, altering air mass velocity components), supply of energy (direct solar power, indirect wind or hydroelectric power or solar powered airplane) and environment improvements (reclaiming wasteland, creating greenhouse farms, reducing bad weather damages, reducing fossil and nuclear fuels usage). Included in SWMS applications is an invention of a Solar Powered Satellite Airplane (SPSA). SPSA comprises a hinged zero lift solar cell disk supported by two wings as shown in FIG. **4**. These SPSAs can serve as global communication platforms.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** Satellite Weather Modification System (SWMS) key subsystems Functional Flow Overview.

FIG. **2**. External Features of A Typical Satellite Engine (SE). FIG. **2** consists of FIG. **2**A (top view), FIG. **2**B (right side view), FIG. **2**C (front view), and FIG. **2**D, showing a typical panel or antenna gimbal rings arrangement.

FIG. **3**. Satellite Engines (SEs) Orbital Operations Overview.

FIG. **4**. Solar Powered Satellite Airplane (SPSA) Design. FIG. **4** consists of FIG. **4**A, which is a sectional view taken along any of the section lines **4**A—**4**A in FIG. **4**C and looking in the direction of the arrows; **4**B, which is a front view; **4**C, which is a top view; and **4**D, which is a side view.

FIG. **5**. Overview Of A Ground Control Station (GCS) Functions.

FIG. **6**. Techniques To Modify Air Mass Velocity Component.

FIG. **7**. Some Satellite Weather Modification System (SWMS) Applications.

Detailed descriptions of these figures are presented below. Important items in each figure are identified in the text by a bold faced number representing the figure number. It is then followed by a fold faced lower case letter to identify the item in the figure. Example: **4***d* identifies item labeled **4***d* in FIG. **4**.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

While there are shown and described the preferred embodiments of the invention, it is to be distinctly understood that the invention is not limited thereto, but may be otherwise variously embodied and practiced within the scope of the appended claims.

To facilitate an understanding of the invention, a number of features are identified herein by letter(s) and a number inside a bold square bracket, as: [letters/number] or [letter-number/number]. Letter(s) or letter-number before a/0 identify major features of the invention. Each non-zero number following the / represents a feature that, while important, is less important than the major features. The major features are:

[SWMS/O] = Features relating to Satellite Weather Modification System (SWMS) designs.
[SE/0] = Features relating to Satellite Engine (SE) designs.
[OP/O] = Features relating to SEs operations.
[RSD/O] = Features relating to Remote Sensing Devices (RSDs) integration.
[GCS/O] = Features relating to Ground Control Stations (GCSs) designs.
[C/O] = Features relating to control energy beam directions.
[F/O] = Features relating to Frequency Agile and Intensity Agile energy beams' selections.
[W#/O] = Features relating to SWMS basic weather modification techniques (# = 1, 2, 3, 4).
[A#/O] = Features relating to SWMS weather modification applications and non-weather related applications (# = 1, 2, 3, 4, 5, 6).

A stand-alone bold faced number followed by a bold faced lower case letter refers to a correspondingly labeled item in the figure identified by the bold faced number. Example: **3***c* represents an item identified by **3***c* in FIG. **3**.

V.1 [SWMS/#]: Features Relating to Satellite Weather Modification System (SWMS) Design

A major feature [SWMS/0] is covered in this section. Five additional features [SWMS/1], . . . , [SWMS/5] are covered in separate paragraphs.

An elaboration of the features is set out below:

[SWMS/1]

The invention employs satellites to harness the solar energy and use this energy to modify selected local weather conditions and/or supply power to various non-weather related applications.

[SWMS/2]

The SWMS modified local weather conditions are, under certain situations, used to modify global weather conditions.

[SWMS/3]

This Satellite Weather Modification System (SWMS) includes the following three key subsystems:

Satellite Engines (SEs) **1***e*.

Remote Sensing Devices (RSDs) **1***c*.

Ground Control Stations (GCSs) **1***d*.

[SWMS/4]

Most SEs are in earth orbits, but some SEs can be installed on land, or airplanes or on ships.

[SWMS/5]

In an SWMS the energy and information flow between sun **1***a*, earth **1***b*, RSDs **1***c*, GCSs **1***d* and SEs **1***e*, as represented in FIG. **1**, are identified and listed below:

1f	Solar energy from the sun to the SEs.
1g	Solar energy from the sun to earth.
1h	Solar activities, such as sun spots, which can affect earth's weather and which are measurable by instruments.
1i	Reflected solar energy beams and/or frequency agile energy beams discharged from SEs to earth surface or into the atmosphere or to deep space or to Solar Powered Satellite Airplanes.
1j	Coded solar or frequency agile energy beams reflected back to SEs instruments or to RSDs instruments.
1s	Solar energy beams or frequency agile energy beams from one SE to another SE.
1k	Solar energy or frequency agile energy reflected back to SEs' reflector panels or the SEs' solar cell panels.
1l	Energy or signals from earth or from atmosphere received by passive RSDs.
1m	Signals transmitted and received by active RDSs.
1n	Time and space tagged measurement data transmitted from RSDS to GCSs at regular intervals.
1p	Command and control messages from GCSs to RSDs.
1q	Status reports from SES to GCSs at regular intervals.
1r	Time tagged detailed assignments (each energy beam's characteristics and its AAP (Adjusted Aim Point) trajectory) for each SE from GCSs at regular intervals.
1t	Desired local and global weather condition requests.
1x	Data and status display to off-line devices.
1y	Off-line analysis to update GCS math models, algorithms, operations and library data base.
1z	Data flow between GCSs. Each GCS takes its turn to coordinate the activities of all GCSs.
1u	Human (manual) controls.

V.2 [SE/#]: Features Relating to Satellite Engine (SE) Design

A major feature [SE/0] is covered in this section. Six additional features [SE/1], . . . , [SE/6] are covered in separate paragraphs.

[SE/1]

SEs can have any shape. In this description it is assumed that the basic structure frame of each Satellite Engine (SE) has an outer contour resembling a flat rectangular box of dimension L (Length)×W (Width)×H (Height), where H is the smallest dimension. All six outside surfaces of this flat box are either fully or partially covered with reflecting materials.

[SE/2]

On top of each L×W surface is an array of n×m panels.

[SE/3]

one side of each n×m panel is made of a reflecting material. It is used to reflect solar rays or laser lights. The other side of each n×m panel is made of solar cells. They are used to convert solar energy into electrical currents.

[SE/4]

Each n×m panel is independently mounted on gimbals on top of each L×W surface. The construction is in such a way that each one of the n×m panels has at least two independent degrees of attitude freedom, **2***p* and **2***r*, with respect to the SE structure frame **2***f*.

[SE/5]

FIG. **2** illustrates n×m panels on each L×W side of a Satellite Engine structure frame. Gimbals rings on SE's L×H and W×H sides **2***a* **2***b* **2***c* **2***d* are designed to provide independent attitude controls of antennae or lamps or any direction pointing devices. Some antennae are used to discharge frequency agile and intensity agile energy beams to earth. Some antennae are used to transmit or receive frequency agile energy beams between SEs. Other antennae are used for communication purposes. Lamps are used to discharge to earth infrared radiations, laser lights or incandescent lights. The number of side gimbals antennae or devices are not limited to only four **2***a* **2***b* **2***c* **2***d* as illustrated in FIG. **2**.

[SE/6]

Additional features displayed in FIG. **2** are identified as follows:

2f	SE structure frame. The LxWxH box.
2h	A typical set of gimbals rings which measure and control each reflector/solar-cell panel's attitudes 2r 2p with respect to SE structure frame 2f.
2p	One of the two degrees of attitude freedom of each panel with respect to SE structure frame.
2r	One of the two degrees of attitude freedom of each panel with respect to SE structure frame.
2q	Reflector/solar-cell panel's possible third degree of attitude freedom with respect to SE structure frame. This will require larger spacing between panels.
2a	Frequency agile and intensity agile RF or MMW or Microwave energy pulse train transmitting antennae.
2b	Reflector/solar-cell panels.
2c	Gimbals mounted infrared lamps or incandescent light lamps or laser antenna
2d	Reflector/solar-cell panels.

In addition, each SE has a number of subsystems residing in its structure frame **2*f***. They are not shown in FIG. **2**, but they are identified below as:

2w	Momentum wheels or other means are used to control and maintain attitude stabilization of SE structure frame 2f with respect to inertial space (see feature (C/#] below)
2n	Navigation subsystem.
2p	Energy transformation subsystem: Transform dc current from solar cells into infrared, frequency agile and intensity agile energy pulses (see features [F/#]).
2c	Computer subsystem.
2z	Communication subsystem.
2i	Retractile receiver designed to receive energy beams from other SEs.
2y	Power regulator.
2e	Energy storage devices are used to store solar energy collected when SE is outside earth's shadow. This energy can be used when SE is inside earth's shadow.
2u	Optical camera package (optional or as part of RSDs).
2v	Synthetic Aperture Radar package and antenna (optional or as part of RSDs).
2w	Thermal imaging camera package (optional or as part of RSDs).
2x	Infrared camera package (optional or as part of RSDs).

V.3 [OP/#]: Features Relating to SEs Orbital Operations

A major feature [OP/1] is covered in this section. Ten additional features [OP/1], . . . , [OP/10] are covered in separate paragraphs.

[OP/1]

As a minimum SWMS configuration, all orbiting SEs are placed in a pair of non-coplanar orbits. These orbits are inclined slightly with respect to each other. In this case, all SEs are apportioned about equally to and distributed uniformly along these two orbits. If both orbits are rotated into a single plane, one orbit will always be slightly higher than the other orbit. The orbits are thus nonintersecting and preferably noncoplanar. Unless otherwise specified, the following descriptions will be for SEs operations on a pair of nonintersecting-noncoplanar orbits.

[OP/2]

At the center of each SE will be the origin of two coordinate systems both moving with the SE along its orbit. One set of solar-fixed axes has one axis that constantly points at the center of the sun. These coordinate axes have an average angular rate of one revolution per year with respect to inertial space. Another set of axes are fixed with respect to the SE structure frame. During normal operations that set will continuously tilt slightly with respect to the solar-fixed axes as required by the mission.

A third set of completely inertial coordinate axes is needed to relate vectors from one set of solar-fixed axes to another.

[OP/3]

In a typical SWMS operation, each SE **3*n*** in the lower orbit maintains its n×m solar reflector panels (on one L×W surface) facing the general direction of the sun. Simultaneously, each lower orbit SE's other L×W surface will have its n×m solar cell panels facing away from the sun. At the same time each SE **3*m*** in the higher orbit will have its n×m solar cell panels (on one L×W surface) facing the general direction of the sun. Its other n×m solar reflectors (on its other L×W surface) will be facing away from the sun.

Each SE experiences two modes of operation during each orbit around the earth. These two modes are defined according to the position of the SE which is inside or outside the earth's shadow. Consider these two cases:

[OP/4]

First, when SEs are outside earth's shadow: In this case the SEs' reflector/solar-cell panel arrangements are as specified in section [OP/3]. These arrangements allow incoming solar rays **3*a*** from the sun to be reflected as shown at **3*b*** from the lower orbit SEs' reflectors to SEs reflectors on the higher orbit before finally being re-reflected as solar rays **3*c*** to earth.

[OP/5]

The electricity generated by the higher orbit SEs' solar cell panels is used to supply each SE's internal needs. Excessive electricity is transformed to different forms of energy beams and discharged to earth via antennae or lamps or stored for later use. At the same time, each lower orbit SE's **3*n*** solar cell panels on one of its L×W surfaces are facing away from the sun. These solar cells receive solar rays **3*r*** reflected from earth or **3*b*** reflected from other SEs. Electricity generated by these solar cell panels is used to supply each SE's internal needs. Any excess electricity is transformed to different forms of energy beams and discharged to earth via antennae or lamps or to another SE or stored for later use.

[OP/6]

Second, when SEs are inside earth's shadow and when solar or laser rays are required in the shadow: In this case, selected SEs in the shadow and in both orbits **3*m***' and **3*n***' have their n×m reflector panels facing away from their respective SE structure frames. These SEs are identified as **3*m***' and **3*n***' in FIG. **3**. This arrangement allows solar rays or laser beams to be passed alternately between these SEs **3*m***' and **3*n***'. This scheme moves energy beams **3*z*** in a zig-zag pattern into the earth's shadow **3*t*** before discharging to earth **31**' or to a high flying SPSA **3*p***.

[OP/7]

Some SEs are equipped with large capacity energy storage devices. Energy collected and stored during daytime can be discharged during nighttime.

[OP/8]

FIG. **3** illustrates a sample case of two nonintersecting-noncoplanar orbits slightly inclined with respect to the equatorial plane. In FIG. **3**, each SE is represented by three short dashes parallel and next to a longer dash spanning the three short dashes. SEs on the higher orbit **3*h*** are labeled **3*m***. SEs on the lower orbit **3*g*** are labeled **3*n***. The three short dashes or **3*m*** **3*n*** represent the L×W side of an SE with its n×m solar cell panels facing away from the SE structure frame. The corresponding longer dash of **3*m*** or **3*n*** represents the L×W side of an SE with its n×m reflector panels facing away from the SE structure frame. In general, when SEs are outside earth's shadow **3*t***, all SEs **3*m*** in the higher orbit **3*h*** have their solar cell panels (three short dashes) facing the general direction of the sun. Similarly, all SEs **3*n*** on the lower orbit **3*g*** have their reflector panels (one long dash) facing the general direction of the sun.

[OP/9]

Other features and labels in FIG. **3** are identified as follows:

3a	Solar rays directly from the sun.
3b	Solar rays reflected once from one SE to another SE or to earth.
3c	Solar rays reflected twice from two SEs (3n and 3m) before being reflected to earth or to an SPSA.
3d	Dash lines are used to represent the path of frequency agile & intensity agile RF, MMW energy beams, infrared radiations, laser beams or incandescent lights emitted from SE antennae or lamps.
3e	Earth's direction of rotation about its spin axis (earth being viewed from a position over the northern hemisphere).
3f	Direction of earth's orbit path around the sun (earth being viewed from a position over the northern hemisphere).
3g	Lower orbit of a typical pair of nonintersecting-noncoplanar orbits.
3h	Higher orbit of a typical pair of nonintersecting-noncoplanar orbits.
3i	Average velocity vector of an air mass independent of current SEs actions.
3j	Average velocity vector of an air mass induced by current SEs actions.
3k	Vector sum of 3i and 3j.
3l	Earth's land surfaces.
3l'	Illuminated sports stadium (e.g., a stadium lighted during night games) or orange groves warmed by solar rays 3z during freezing nights.
3m	SE in higher orbit 3h. Its nxm solar cell panels (on one LxW side) face the general direction of the sun 3a. Simultaneously, its other nxm panels have their reflectors facing away from the sun.
3n	SE on the lower orbit 3g. Its nxm reflector panels (on one LxW side) face the general direction of the sun 3a. Simultaneously, its other nxm panels have their solar cells facing away from the sun.
3m'	Selected SEs in higher orbit 3h in earth shadow. These SEs are used to transmit solar or laser rays 3z into the shadow.
3n'	Selected SEs in lower orbit 3g in earth shadow. These SES are used to transmit solar or laser rays 3z into the shadow.
3w	Earth's ocean, lake or other wet surface.
3p	High altitude and long endurance Solar Powered Satellite Airplanes (see FIG. 4). SPSA continuously receives solar rays or MMW energy or laser beams from SEs. SPSA can also receive energy from ground.
3q	Cloud or air mass whose compositions, thermodynamic and dynamic properties are being modified by SEs.
3r	Reflection of solar enerqy from the clouds, ocean or land back to space.
3t	Earth's cone shaped shadow.
3z	Solar rays reflecting alternatively between SEs 3m', 3n' on different orbits 3h, 3g, when these SEs are inside earth's shadow 3t. These energies 3z can be used to power SPSAs 3p or to warm cold ground patches 3l' at night.

[OP/10]

The n×m panels may be arranged in a way slightly different from the one described so far. It is possible to mix the number of solar-cell panels and the number of reflector panels on each L×W side of each SE. This arrangement applies to all SEs in both orbits **3***h*, **3***g* as follows: Each L×W side of each SE will have (n×m−k) reflector panels and k solar-cell panels facing away from its SE structure frame, where k=0, 1, . . . , (n×m). For each L×W side, the exact k number is dependent on each SE's internal power consumption need and its mission requirements. This arrangement is especially useful for SEs in geo-synchronous orbit.

V.4 [RSD/#]: Features Relating to Remote Sensing Devices (RSDs) Integration

A major feature [RSD/0] is covered in this section. Two additional features [RSD/1] and [RSD/2] are covered in separate paragraphs.

[RSD/1]

Remote Sensing Devices (RSDs) **1***c* comprise millions of independently operated sensors. These RDSs are located on the ground, on the water, in the air, on SPSAs, or on SEs. RSDs perform independent measurements such as monitoring sunspots, measuring the composition and thermodynamics properties of a particular atmospherical air mass, monitoring the effect of SEs' energy beams, etc.

[RSD/2]

Each sensor continuously makes redundant measurements. Each measurement is time and location tagged and transmitted to a specified Ground Control System (GCS) **1***d* computers at regular intervals. These data are in standard formats so that they can be quickly correlated, analyzed and accepted by various algorithms and mathematical models in the GCSs **1***d* computer network.

V.5 [GCS/#]: Features Relating to Ground Control Stations (GCSs) Designs

GCSs provide the guidance of each energy beam. This includes the selection of each energy beam's characteristic and its corresponding Adjusted Aim Point (AAP) trajectory. A major feature [GCS/0] is covered in this section. Three additional features are [GCS/1], GCSs subsystem overview; [GCS/2], simplified GCS tasks design; and [GCS/3], a typical matured GCS subsystem tasks design and partition.

[GCS/1] GCS Overview

Each Ground Control Station (GCS) **1***d'* includes a network of interconnected supercomputers, electronic libraries, data receivers, data storage devices, data transmitters, visual display devices and control consoles. There are hundreds of GCSs **1***d* in the SWMS. Each GCS monitors weather conditions within a designated region of earth. Each GCS receives designated RDSs measurements **1***n'*, local weather requests **1***t'* and data from other GCSs **1***z*. Each GCS also transmits estimated tasks **1***r'* to a specified group of SEs and receives data from other GCSs **1***z*. Data generated by each GCS are broadcast to all other GCSs **1***z*. Therefore, each GCS will have detailed global weather information and status of all SEs at discrete time points. Each GCS will take its turn to be the master GCS, which coordinates the operations of all GCSs in the SWMS.

(NOTE: the notations **1***d'*, **1***n'*, **1***r'*, **1***t'* represent designated GCSs, selected RSDs' data, specified SEs' tasks and local weather requests respectively. Their corresponding notations without the ' given in FIG. **1** are for all GCSs, all RSDs data, all SEs tasks and all weather requests.)

[GCS/2] Simplified GCS Tasks Designs

In most SWMS applications, SEs' assignments involve only reflecting solar rays. This is the case for SWMS during its initial stage of development. In this stage of development a GCS's principal task involves defining AAPs (Adjusted Aim Points) trajectories of each energy beam (centerline of each reflected solar ray) in some earth fixed coordinate system.

The available solar energy and the directions of incoming and reflected solar rays to and from each n×m reflector panel can be calculated as a function of time. These calculations use measurements of SE structure frame orientations with respect to inertial space, orientation measurements of each reflector panel gimbals with respect to its SE structure frame and orbital mechanics.

On the other hand, the desired aim point of each reflected energy beam and its trajectory are both specified by GCSs. This is done by distributing the aim points over the surface that is to be warmed by the solar rays. These aim points are then adjusted to take into account the atmospherical refraction and absorption of each energy beam and transform desired aim points to a corresponding set of AAPs (Adjusted Aim Points). A set of AAP vectors will be defined in an earth-fixed coordinate system. Each AAP point will be at the tip of its corresponding AAP vector. Next, AAPs trajectories are defined based on the amount of energy and rate of energy that is to be deposited onto the desired space. These estimated AAPs trajectories are transmitted to their corresponding SEs.

An LOS vector is defined as a vector from the center of any reflector panel to its corresponding AAP. Both this LOS vector and its corresponding reflecting solar ray vector are expressed in the same coordinate system, based for example on the SE structure frame fixed axes. Then the vector difference between these two vectors at a given time defines an error vector. This error vector specifies the required change of available energy beam's direction at that time.

The unit vector of each desired direction will be transformed to SE structure frame fixed coordinate axes. Assuming the SE structure frame follows a predetermined orientation schedule with respect to inertial space, then the desired gimbals angles of each reflector panel can be calculated from its unit desired direction vector. Also, each desired direction vector must satisfy the solar rays' availability constraints.

These computations must be repeated continuously many times a minute. This will provide the required error signal to the stepping motors to torque each gimbals ring. This scheme will control each reflected solar ray to follow its AAP trajectory in a timely fashion.

[GCS/3] Typical Matured GCS Tasks Designs and Partitions

FIG. **5** graphically illustrates typical SEs' assignments (energy beams' characteristic and their AAPs trajectories) estimation process designed for a more matured SWMS. Key functions are identified by blocks and connected by high speed data busses (dashed lines). The main processing sequence is: **5*b*** **5*d*** **5*e*** **5*f*** **5*e*** **5*k*** **5*m*** **5*n*** **5*b***. Other functions of FIG. **5** are identified below:

5*a* A GCS library. This includes individual mathematical models **5*q***, Integrated global-weather/SWMS (Satellite Weather Modification System) model **5*p***, Historical weather statistics **5*i***, Encyclopedia of energy beam transmission, refraction, absorption, and reflection characteristics in all kinds of weather conditions **5*t***, Encyclopedia of meteorology **5*s***, past SEs weather modification performance data **5*v***, Catalogued encyclopedia of SWMS Satellite Engines performance **5*f*** permitting rapid search for SEs task assignments that will satisfy the new weather modification constraints specified by **5*e***.

5*q* Individual models include: Sun, sunspots, solar radiation, lunar orbital motion, solar wind intensity distribution, earth orbital motion, earth's gravitational model, atmospherical layer models, ocean current models, earth surface and subsurface models, natural and man-made discharges, absorption, refraction models, etc. Satellite Engines model, SE system performance models, interactions between atmosphere models and all other models, etc.

5*i* Historical global and local weather data statistics, including such data as annual rainfall distributions, annual temperature distributions, seasonal weather conditions, etc.

5*t* Encyclopedia of the interaction of energy beams with atmosphere, land mass and sea surfaces.

5*f* Encyclopedia of SEs performance data classified according to: energy types and characteristics, guidance law employed (AAPs' trajectories), initial atmospherical conditions, required atmospherical conditions changes, Satellite Engines sub-groupings. These data are continuously updated by off-line simulations **1*y*** and by data from actual SEs past performances **5*v***. Data **5*f*** output back to **5*e*** will include SEs groupings, each energy beam characteristics and AAPs' trajectories, all expressed as functions of time.

5*l* Estimate the desired weather conditions in next (Tb,Tc) interval based on past weather condition statistics. Desired weather is expressed in terms of weather characteristic vectors for each affected weather cell.

5*g* Special desired weather condition requests. All requests are expressed in terms of weather characteristic vectors sequences for each weather cell. Both weather cells and weather characteristic vectors are defined in **5*d***.

5*b* Update integrated mathematical model using designated RSDs **1*n*'**, designated SEs' status reports **1*q*'**, and updated data from other GCSs **1*z***. The results of these updates yield an up-to-date integrated global weather math model with Satellite Engines' math models integrated in the total model. The resultant model is to be used for further extrapolations **5*d***, for storage in local GCS library **5*a*** and for broadcasting to all other GCSs **1*z***.

5*c* Estimations of selected SEs' task assignments for the next (Tb,Tc) interval based on anticipated requirements from **5*l*** and **5*g***. These estimates are passed on to **5*d***.

5*v* Off-line evaluation of SEs performances in the previous (Tb,Tc) interval using actual RSDs measurements **1*n*'** and previous cycle SEs' assignments **1*r*'** adjusted by actual SEs status reports **1*q*'**. Results of SEs performance evaluations are used to update GCS library data **5*t***, **5*f*** and **5*q***.

5*d* Forward extrapolation of integrated mathematical model **5*b***, from t=Ta to t=Tc, in equal dT increments, where dT=(Tc−Ta)/N and N=a large even integer. If the actual RSDs measurements for the (Ta,Tb) interval are in agreement with previously estimated weather parameters, then this extrapolation process can be reduced to only the (Tb,Tc) interval.

The atmosphere is subdivided into weather cells. The average thermodynamics, dynamics and air composition parameters inside each weather cell are represented by a vector called the weather characteristic vector. Each weather cell is represented by its weather characteristic vector for a fixed time duration.

5*e* First, find the required weather changes by taking the differences between the extrapolated weather conditions from **5*d*** and the corresponding desired weather conditions from **5*h***. This is done by manipulating the corresponding weather characteristic vectors.

Next, initialize a search in **5*f*** for the SEs' task assignments during the (Tb,Tc) interval. SE task assignments from **5*f*** will include parameters which define each energy beam's characteristics and its Adjusted Aim Point (AAP) trajectory. This search uses the initial weather conditions from **5*d***, required weather changes from **5*d*** and **5*h***. However, a sequence of desired weather conditions from **5*h*** is selected at reduced constraint levels. This will ensure that at least one set of the answers found from **5*f*** will later satisfy the criteria in **5*k***.

Found in **5*f*** are SE's task assignments which include each one of its energy beam's characteristics as a function of time and their corresponding Adjusted Aim Point (AAP) trajectories.

Each SE assignment parameter is found by matching stored **5***f* energy absorption patterns or thermodynamic changes patterns with their corresponding required change patterns **5***e*.

5*k* The SEs' tasks assignments found in **5***f* are evaluated by performing parallel simulations. The results of these simulations should determine which set of SEs assignments best satisfies the desired weather conditions imposed on the SEs by **5***h*. All calculations are done in terms of weather characteristic vectors at the weather cells' levels **5***d*.

5*m* Define detailed Satellite Engines' task time lines based on optimal selection from **5***k*. These assignments are transmitted to the corresponding SEs **1***r*'. A second set of these assignments is sent to **5***c* for the next computation cycle. A third set of these data is sent to the GCS library data bus to be broadcast as indicated at **1***z* to all GCSs in the SWMS. This last step is necessary to take care of conditions when a GCS is reassigned to manage a different set of SEs in the next computation cycle.

5*n* Initialize the next computation cycle. The current (Tb,Tc) interval is shifted down to become the next (Ta,Tb) interval, and a new (Tb,Tc) interval is selected with the old Tc set to equal to the next Tb. The next computation cycle repeats at **5***b*.

The descriptions set out above outline a typical process to define SEs grouping, each energy beam type, each energy beam's physical characteristics and its Adjusted Aim Point (AAP) trajectory. These parameters are transmitted to their corresponding SEs **1***r*'.

NOTE: **1***x*, **1***y*, **1***z*, **1***r*', **1***q*' and **1***n*' refer to the same items identified in FIG. **1**. The prime ' denotes that these data belong to only a subgroup of SEs or subgroup of RSDs.

V.6 [C/#]: Features Relating to Control Energy Beam Directions

One major feature [C/0] is covered in this section. Two additional features [C/1] and [C/2] are covered in separate paragraphs.

[C/1] Overview

Each SE shall release its energy beams in a timely fashion following its AAP trajectory as specified by its GCS **5***m*. SE's control subsystem aims each energy beam at its AAP (Adjusted Aim Point) and makes each energy beam follow its AAP trajectory in a timely fashion.

[C/2] Direction Controls

This energy beam directional control task is partitioned into two sub-tasks. First, control the orientation of SE's structure-frame axes with respect to inertial space. This is done by using inertial flywheels or other means. Second, control the orientation of solar-reflector/solar-cell panels, antenna dishes, or lamp axes with respect to the SE's structure-frame axes. This is done by measuring the actual gimbals angle settings and torquing each gimbals ring to its desired orientation. Each energy beam's desired orientation at a given time is defined by its unit vector from reflector (or antenna or lamp) center to its AAP at that time. Using, for example, the directional cosine technique, these desired unit vectors can be transformed into desired gimbals angles. A more detailed description on how this is done has been presented above at [GCS/2].

V.7 [F/#]: Features Relating to Energy Beam Frequency and Intensity Selections

A major feature [F/0] is covered in this section. Seven additional features [F/1], . . . , [F/7] are covered in separate paragraphs.

Solar rays will be the primary energy beams discharged by the SEs. However there are times when other types of energy beams are required to penetrate a cloud layer, or to heat up a specified air mass of specific composition. In these cases, frequency agile and intensity agile energy beams are used. The frequency of an energy beam determines its ability to penetrate a layer of atmosphere of a specified composition. It also determines the degree of absorption of a given frequency energy beam by an air mass of a particular composition. Weather cells air mass compositions are estimated by Remote Sensing Devices (RSDs).

[F/1]

A specific energy beam's frequency and intensity will be selected to satisfy a given depth of atmospheric penetration and to yield a specified energy absorption contour or temperature elevation contour.

[F/2]

The change of energy into heat is monitored by RSDs, such as infrared sensors or thermal imagery cameras. Or it can be estimated from specially designed ground receivers. These receivers measure the presence of frequency agile energy beams which are frequency, amplitude or phase modulated. These RDSs data are used by GCS or by SEs directly, thus enabling adaptive adjustments of energy beams' frequencies and intensities.

[F/3]

Energy intensity at a given location is also controlled by energy beam guidance laws which specify each energy beam Adjusted Aim Point's (AAP's) trajectory, the speed AAP moves along its trajectory, dwell times, locations on an AAP trajectory and the shape of an AAP trajectory.

[F/4]

Selection of each frequency agile energy beam's frequency rests on the knowledge of the energy beam's attenuation due to atmospherical absorption, reflection and refraction. These data are stored in the GCS electronic library **5***t* as dB/Km (or watts or % transmission loss per kilometer of the energy beam path) vs frequencies for different atmospheric compositions.

[F/5]

For a given atmospheric composition the dB/Km values show a sharp drop within certain narrow frequency bands called windows (Radar and the Atmosphere by A. J. Bogush, Jr., Artech House 1989). Near the left end of each window, the parameter dB/Km experiences a sharp drop in value (dB/Km/f<<0). Near the right end of each window, the parameter dB/Km experiences a sharp rise in value (dB/Km/f>>0). The frequency of each frequency agile pulse (or beam) is selected near either end of these frequency windows to permit injection of frequency agile energy pulses into selected regions of the atmosphere.

[F/6]

Energy levels are selected to achieve the rates at which the accumulated energy absorption will change the thermodynamic and dynamic parameters of the atmosphere in a predetermined way. An example of such a rate is the rate of average temperature rise within a group of weather cells.

[F/7]

Furthermore, the energy level must satisfy safety requirements (Introduction to Radar Systems by M. I. Skolnik, McGraw-Hill Book Co. 1962).

V.8 [W#/#]: Features Relating to Basic Weather Modification Techniques

There are four major features [W1/0], . . . , [W4/0] covered in respective sections. A total of 12 (=6+2+2+2) additional features are set out separately. These additional features are:

[W1/1], . . . , [W1/6],
[W2/1], [W2/2],
[W3/1], [W3/2],
[W4/1] and [W4/2].

Basic techniques employed by SWMS to modify weather are listed below. Other weather modification requirements can be met by making different combinations of these basic techniques. These techniques are identified as basic weather modification techniques #1 through #4 ([W1/0], . . . , [W4/0]).

V.8.1 [W1/#]: Features Relating to Modifying Global Weather Conditions

This technique employs a very large number of Satellite Engines (SEs) to modify global weather conditions by blocking or redirecting solar rays. One major feature [W1/0] is covered in this entire section. Six additional features [W1/1], . . . , [W1/6] are covered in separate paragraphs.

[W1/1]

This method involves using millions (or even billions) of Satellite Engines (SEs) to block or redirect solar rays. Typically, this requires a large number of low inclination and non-coplanar orbits near the equatorial plane. When the earth requires cooling, the Ground Control Stations (GCSs) simultaneously command all SEs to rotate their n×(m−k) (k=0, 1, . . . <<m) reflector panels (on one L×W side) to face the general direction of the sun and away from earth. These SEs block part of the solar energy from reaching the earth by reflecting the solar energy away from earth and thus assist the earth's cooling process.

Each SE will reserve k solar cell panels (along with n×(m−k) reflector panels) to face the sun. These solar cell panels are used to generate electricity for the SE's internal use. The value of k is such that k=0, 1, 2, . . . , <<m. The k=0 case implies that solar cells located on the back side of each reflector panel or on its other L×W surface can generate sufficient electricity for the SE's internal use.

[W1/2]

The reflected solar rays' guidance is done by specifying the Adjusted Aim Points (AAPs) of each reflected solar energy beam and trajectories of these AAPs in deep space away from earth. In this case the AAPs can be simply computed as the line-of-sight aim points, because the reflected solar rays will have little or no interference (refraction) by the atmosphere.

[W1/3]

It is to be noted that when the equatorial regions become cooler, the average temperature differences between the polar regions and the equatorial regions are reduced. Therefore this technique may be used to modify global weather patterns or to create favorable local weather conditions which can be further modified by SWMS.

[W1/4]

When controlled cooling is not required, GCSs command some or all SEs to direct their collected solar energy to other SEs or to earth directly. Again, this is done by specifying the AAPs of each energy beam and their trajectories to the desired locations on earth or at specified Satellite Engines' reflector panels or solar cell panels. This process selectively cools certain regions but at the same time heats up other regions. This technique can also be used to supply energy to specific devices. All these tasks are under GCSs control.

[W1/5]

If these temperature differential regions are sufficiently close, an air mass motion is introduced which forces the air mass to move from the high pressure region to the low pressure region. This technique can be used to move an air mass of specific composition from one location to another.

This technique can also be used to modify the jet stream path and therefore modify the weather on either side of the jet stream.

[W1/6]

Distributing AAPs over a small wet surface and aiming solar rays at these AAPs will cause evaporation. This will increase the humidity of air above the wet surface. As the humid air rises to higher altitudes clouds will form. These clouds can be used to cool local regions by blocking the sun's rays. They can also cause precipitation.

V.8.2 [W2/#]: Features Relating to Modifying Local Weather Conditions

This technique is similar to feature [W1/6] but requires far fewer Satellite Engines (SEs). Also, SEs orbits are paired as specified in feature [OP/0]. One major feature [W2/0] is covered in this entire section. Two additional features [W2/1] and [W2/2] are described in separate paragraphs.

[W2/1]

This technique can be used to warm a local region. This is done by distributing AAPs (of all SEs' reflected energy beams) over the region to be warmed. Each reflected energy beam will be assigned to dwell at a given AAP for a given duration, or each AAP trajectory will be limited to circle within a desired region.

[W2/2]

This technique can be used to create a high humidity air mass or to form clouds. This is similar to feature [W2/1] above, except that the reflected solar rays are aimed at AAPs distributed over a wet surface, such as a lake or a patch of ocean. This process is originated by Ground Control Stations (GCSs) defining the AAP trajectory of each energy beam over the wet surfaces. Satellite Engines (SEs) then reflect solar rays to their respective AAPs. This process is essentially the same as one that occurs in nature, except that both the wet surface area and the timing are selected and controlled by SWMS. Also, the intensity of the solar ray can be made more concentrated than what occurs in nature. This process will increase the moisture content of the air mass above the heated wet surface. As the high humidity air rises to higher altitudes, it begins to cool and form clouds.

V.8.3 [W3/#]: Features Relating to Moving an Air Mass Upwards

One major feature [W3/0] is covered in this entire section. Two additional features [W3/1] and [W3/2] are covered in separate paragraphs.

[W3/1]

This technique is designed to initiate and/or modify an air mass's upward motion. This is done by adaptively aiming energy beams of specified characteristics at specified AAPs. These AAPs are distributed in a vertical column inside or near the air mass that is to be moved. The type, frequency, intensity and AAP trajectory of each energy beam are adaptively selected based on sensors' feedback measurements which lead to optimal upward movement of the air mass due to energy absorption. Combinations of energy beam characteristics with guidance law (AAPs trajectories) options are simulated to obtain an optimum combination. One such criterion to judge the optimum combination can be a criterion which determines the rate of climb at which this air mass will rise to higher altitudes.

[W3/2]

Some SEs are located on earth's surface for this purpose. Other SEs may be in the air or move with the rising air column. These ground based or sea based SEs are used to heat the air column from below.

V.8.4 [W4/#]: Features Relating to Modifying an Air Mass's Horizontal Velocity Component

One major feature [W4/0] is covered in this entire section. Two additional features [W4/1] and [W4/2] are covered in separate paragraphs.

The best way to transport an air mass of specific composition and thermodynamic properties is to allow it to be carried by wind currents that exist in nature at that time. However, natural wind does not always satisfy weather modification requirements. The following techniques to transport an air mass are presented.

[W4/1]

This technique includes creating a pressure differential on either horizontal side of the air mass to be moved. This technique is similar to the one discussed in section [W1/5], except in this case in air mass size and movement are very localized. This technique requires unequal distribution of energy into two adjacent sides of the air mass to be moved. This is done by unequal concentrations of energies, AAPs, or energy beams' dwell times on either side of an air mass.

[W4/2]

This case involves concentrating AAPs trajectories along a desired direction of air mass motion. FIG. **6** illustrates this concept. Consider the case where an air mass has no initial lateral motion component. The objective is to move the air mass near **6***x* to points near **6***y*. First, define this desired direction by an arrow **6***v* relative to earth **6***e*, which may be inclined at an angle with respect to the local gravity vector. Next, imagine a large tube **6***i* enclosing the air mass to be moved and with the desired directional arrow **6***v* along tube's centerline **6***x*-**6***y*. Next, define a sequence of AAPs (**6***a*', **6***b*', **6***c*', **6***d*', . . .), such that the maximum energy absorption of each energy beam will be made to concentrate near the centerline of the tube (at **6***a*, **6***b*, **6***c*, **6***d*, etc., respectively). All these AAPs are estimated by GCSs and transmitted as assignments to the SEs **6***s* on orbits **6***h* or **6***g*. Note: each **6***s* point in FIG. **6** can represent many SEs. These SEs will first (at t=ta) concentrate all their energy beams at AAP **6***a*' near point **6***x*. This large input of energy will cause the air mass near **6***a* to absorb the energy and expand rapidly in all directions. Assume a constant temperature contour (resulting from absorption of these energy beams) can be represented by a tear shaped figure labeled **6***k*. Next (at t=tb), let these SEs shift their common aim point to an adjacent AAP at **6***b*'. This will result in rapid heating of another air mass centered at **6***b*. This will cause another tear shaped constant temperature contour labeled by **6***l*. Continuing this process is like producing a sequence of small "explosions" along the imaginary tube's centerline. The size of each "explosion" is controlled by the number of SEs (or energy beams) shearing the same AAP at a given time. The speed of the induced air mass velocity component along **6***v* also depends on the spacing and rate of change of these AAPs or energy beams dwell times along their AAP trajectories. When energy focus reaches the end of the tube **6***y*, this process can be repeated again starting near **6***x*.

This concept can be explained in another way by considering the rows of small circles in FIG. **6**. Each small circle represents the expansion due to absorption of concentrated energy beams at a given location **6***a*, **6***b*, **6***c*, . . . etc. The small arrows radiating out from the center of each small circle in FIG. **6** represents the direction of the local air velocity. As the energy center moves from **6***a* to **6***b* to **6***c* . . . , the velocity components between energy centers cancel each other out. What is left over is only the velocity component in the desired direction **6***v*. When the energy beams are removed, the surrounding cooler air will rush back into the imaginary tube **6***i* and push the air in the **6***v* direction. This technique will always introduce an air mass velocity component in the local vertical direction. This vertical velocity component may not be a bad feature in many applications, as when moving a humid air mass inland and allowing it to condense to rain. The horizontal velocity component will move the air mass inland. The vertical velocity component will allow the air mass to move to a higher and colder altitude. This will delay the air mass's condensation into rain until it has reached its desired location. If the air mass has an initial lateral velocity component **3***i*, then the final air mass velocity vector **3***k* is the vector sum of its velocity vector caused by its initial velocity **3***i* plus the SWMS induced velocity vector **3***j*.

The best way to use this technique is to first create a rising column of air near **6***y* using techniques described in section [W3/0]. Next, simultaneously applying the teachings at [W3/0] and [W4/2] will cause the air mass inside the imaginary tube **6***i* to feed to the rising air column created by [W3/0].

[A#/#]: Features Relating to Satellite Weather Modification System (SWMS) Applications

There are five major features [A1/0]–[A3/01], [A6/0] respectively covered in separate sections. There are a total of 16 (=0+0+3+0+8+5) additional features respectively covered in separate paragraphs. These additional features are:

[A3/1], . . . , [A3/3],
[A5/1], . . . , [A5/8],
[A6/1], . . . , [a6/5].

Some SWMS applications are designed to employ various combinations of the basic weather modification techniques described in section V.8. Other applications are related to energy supply and solar powered airplanes (FIG. **4**). All applications are designed to offer unique and useful services. All applications are selected to have the potential to compete successfully in the real business world. Some of these SWMS applications are illustrated in FIG. **7** and described below.

V.9.1 [A#/#]: Features Relating to Increasing Precipitation

One major feature [A1/0] is covered in this section.

[A1/0]

High humidity air masses are created by application of techniques specified in sections [W1/6] AND [W2/2] over wet surfaces **7***x* to cause cloud formation. Cloud temperatures are maintained by techniques covered in sections [F/0], [W3/0] and [W4/2]. The air mass is allowed to move to a desired location by natural wind current or by techniques specified in sections [W3/0], [W4/1] and [W4/2]. The cloud is left to cool down by a natural cooling process. This produces precipitation over the desired area. This technique can be applied to many dry regions of the world. Potential application regions are in southern California **7***y*, northern Ethiopia **7***z*, etc.

V.9.2 Omitted

V.9.3 [A3/#1]: Features Relating to Creating Whirlwinds

One major feature [A3/0] is covered in this section. Three additional features [A3/1], . . . , [A3/3] are covered in separate paragraphs.

[A3/1]

Techniques specified in section [W3/0] or [W4/0] can be used to move two air masses in opposite directions (or in the same direction but at different speeds). These air masses are offset by a small distance. This process will create a whirlwind or a small tornado.

[A3/2]

Alternatively, the movement of one of the air masses can be due to natural causes.

[A3/3]

Whirlwind or tornado strength can be increased (decreased) by combining and colliding many smaller whirlwinds rotating in the same direction 7*j* (opposite directions 7*i*), thus creating a stronger (weaker) whirlwind.

V.9.4 [A4/#]: Features Relating to Warming Land, Sea and Air

One independent feature [A4/0] is covered in this section.

[A4/0]

Techniques described in sections [W1/4] and [W2/1] can be used to warm a land mass directly or to warm the air mass immediately above the land mass. This is done by distributing the AAPs over the region of interest. That is, the SEs are commanded to discharge solar rays or infrared radiations at these AAPs for specified durations until the desired average temperature rise has been achieved.

A few degrees rise in temperature, for a few hours during extremely cold winter nights, can save many millions of dollars worth of fruit crop annually in Florida 7*r*, California 7*r* and many farms at high altitude. This same technique can be used to heat large greenhouse farms in the U.S. Northeast 7*w*, where the large demand for fresh farm produce now necessitates importation from great distances, using large amounts of fossil fuels.

V.9.5 [A5/#]: Features Relating to Solar Powered Satellite Airplane (SPSA) Designs and Applications

One independent feature [A5/0] is covered in this section. Eight additional features [A5/1], . . . , [A5/8] are covered in separate paragraphs.

[A5/1]

A Solar Powered Satellite Airplane (SPSA) is disclosed that utilizes the energy beams discharged or reflected from Satellite Engines (SEs) to power its flight at high altitudes. As an illustration of this concept, only solar rays reflected from SEs are considered here. However, a similar system can be designed to receive laser beams or microwave energy beam from SEs. The word SATELLITE in SPSA implies this airplane's dependence on Satellite Engines (SEs) and its ability to fly indefinitely in circles above the clouds and over a fixed land area. This is illustrated by racetrack shaped dash circles 7*t* in FIG. 7.

[A5/2]

FIG. 4 shows a typical SPSA design. This comprises a large hinged solar energy collecting disk 4*d* supported by two lift producing wings 4*w* located on either side of the disk. Arrays of solar cells 4*s* arranged on the disk 4*d* transform solar energy into electrical current. This electricity is used to power two electrical motors 4*m*, located on each wing, which drive two propellers 4*p*.

[A5/3]

Continuously adjusting SPSA headings and adjusting the disk tilt angles 4*c* (disk 4*d* roll angle about SPSA fuselage axis) will ensure that the solar rays reflected from Satellite Engines (SEs) 7*c* are as perpendicular to the disk surface 4*s* as possible at all times. This ensures maximum energy reception by the disk.

[A5/4]

The energy collecting disk 4*d* is designed to produce no lifting force during normal high altitude level flight.

[A5/5]

This zero lift condition is achieved by the combination of three design characteristics: First, the disk 4*d* has a plane of symmetry with respect to both of disk surfaces 4*s*. Therefore, when the angle of attack is zero, this disk will only produce a drag force. Second, during normal high altitude operations at any disk tilt angle 4*c*, this disk 4*d* will be maintained at zero angle of attack by its wings 4*w*. Third, independent adjustable slots 4*j* are arranged over the disk surface. Whenever pressure sensors 4*i* detect a pressure differential developing across the disk, these slots 4*j* will open automatically to let air flow from the high pressure side to the low pressure side of the disk, thus killing the lift force on the disk. Pressure sensors 4*i* are also distributed over the entire disk 4*d* and on both sides of the disk.

[A5/6]

During take-off and landing runs, SPSA's energy collecting disk 4*d* is rotated to be parallel to its two wings as illustrated in FIG. 4. These wings will control and maintain the disk at a non-zero angle of attack position. At the same time pressure sensors 4*i* are turned off. This causes all slots 4*j* to lock in closed positions. This scheme can be used to create lift force on disk 4*d* during selected mission phases, such as during take-off and landing runs.

[A5/7]

Ground Control Stations (GCS) 1*d* are used to estimate which Satellite Engines (SEs) are available to supply power 7*c* to which Solar Powered Satellite Airplane (SPSA) 7*p*. GCSs are also used to estimate the direction and intensity of each reflected solar ray 7*c* as functions of time. GCSs must focus a group of AAPs at the center of each SPSA disk 4*d*. Also, GCSs will estimate the trajectories of these AAPs' common focal points. The trajectory of one subgroup of AAPs' common focal point will become the flight path 7*t* of one SPSA. GCSs will also estimate the disk tilt angle 4*c* of each SPSA. This information is uplinked to each SPSA. Software on-board the SPSA will enable it to fly a flight path 7*t* specified by its AAPs' common trajectory 7*t*. At the same time the SPSA will tilt its disk 4*d* following the tilt angle 4*c* time-line specified by GCSs. Periodically, SPSA will shift to a different set of SEs, a different AAPs' trajectory and a different disk tilt angle time-line as commanded by a GCS.

[A5/8]

FIG. 4 illustrates basic design features of an SPSA. A top view and a front view show an SPSA in a take-off or landing configuration. Also, a cross-section view shows the disk tilting mechanism. Important SPSA features shown in FIG. 4 are identified below.

4b	Electric motor, gear box and lock mechanism.
4c	Solar energy collecting disk 4d tilt angle. Tilt angle is the same as roll angle about the SPSA fuselage axis.
4d	Solar energy collecting disk.
4e	Landing gears.
4f	Fuselage.
4g	Gear to tilt and lock disk at desired angle.
4i	Pressure sensors located near slots 4j and distributed over both sides of the disk.
4j	Slots distributed over the disk. Slots are normally closed. Slots will automatically open to balance any local pressure difference developed across the disk.
4k	Roller rod bearings distributed over the fuselage circumference. They provide smooth tilting (roll) of the disk about SPSA fuselage axis.
4l	Payloads.
4m	Electric motor and gear mechanism used to drive the propellers.
4p	Propellers.
4q	Gear teeth attached to the disk 4d and arranged in a circle around the outer circumference of the SPSA fuselage 4f. These gear teeth are used to transmit torque which drives disk 4d tilt angles 4c.
4r	Rudders.
4s	Solar cell array cover the entire (one or both sides) disk 4d surface.
4t	Vertical tails.
4v	direction of SPSA forward motion.
4w	Wings

V.9.6 [A6/#]: Features Relating to Business Ventures Based on SWMS & SWMS/SPSA Services

One major feature [A6/0] is covered in this section. Five additional features [A6/1], . . . , [A6/5] are covered in separate paragraphs.

[A6/1]

Applications of Satellite Weather Modification System (SWMS) can be organized into unique global business ventures. There are strong demands for the types of services offered by SWMS. The services SWMS offers to the world are unique and non-existing at the present time. Both SWMS manufacture and services will generate new jobs and enhance the earth's environment at the same time. These features further strengthen the Satellite Weather Modification System (SWMS) potential as a useful invention. Therefore these SWMS business ventures are an important benefit of this invention.

[A6/2]

Stock can be issued and offered to the public to raise the necessary funds to finance these ventures. Raised funds will then be used to build prototypes of SWMS subsystems: Satellite Engines (SEs), Ground Control Stations (GCSs), Remote Sensing Devices (RSDs) and Solar Powered Satellite Airplanes (SPSAs).

[A6/3]

Initially a few basic services will be offered to potential customers who can afford to pay for SWMS services. In each orbit each SE can sequentially service many locations below its orbit. Therefore, by simply changing some computer codes these SEs can also service some non-paying customers as a public service.

[A6/4]

Some of the initial services to be offered by SWMS are illustrated in FIG. **7**. Satellite Engines (SEs) distributed in the orbits (**7***h* and **7***g*) are too small to be shown in FIG. **7**. Solar rays **7***a* from the sun are first reflected **7***b* from the SEs in the lower orbit to SEs in the higher orbit before finally being reflected to earth **7***c*. Some initial services to be offered by SWMS are described below:

1. Techniques described in section [A4/0] are used to warm local regions during extremely cold winter days. Potential paying customers are orange growers in Florida **7***r* and California **7***r*, greenhouse farms **7***w*, etc. Potential nonpaying customers are small farmers at high latitudes, etc.
2. Solar Powered Satellite Airplanes (SPSAs) **7***p* (described in section [A5/0]) are used to carry communication relay instruments or weather monitoring equipment **4***l* over local regions. Potential paying customers are communication companies, news services, etc. Potential non-paying customers are public education services, environmental protection agencies, weather services, local police departments, etc. It is to be noted that when an SPSA flies a closed loop pattern **7***t* (dashed line racetrack patterns in FIG. **7**) above a given land region, it can be used to compete for business with satellites in a geo-synchronized orbit. The advantages of SPSA include that these SPSAs are re-usable and closer to earth and each SPSA carries its own reusable launching system.
3. The technique discussed in section [A1/0] is used to bring rain to dry regions in the world. The Satellite Engines' (SEs') tasks are to warm the ocean surface a few miles off the southern California coast **7***x*. These tasks must also be timed with the local ocean wind direction, so that the high humidity air mass created by SEs over the ocean can be carried inland by the wind. To support the energy beams' direction guidance laws, a set of AAPs are defined and distributed over an ocean surface area **7***x*. The trajectories of these AAPs can follow the local water current, be timed in accordance with local wind directions, and avoid local cloud formations. Potential paying customers are southern California water authority **7***y*, etc. Potential non-paying customers are drought victims of Ethiopia **7***z*, etc.

[A6/5]

FIG. **7** illustrates some SWMS applications. Items in this figure are identified below:

7a	Solar rays from the sun.
7b	Solar rays reflected from SEs in lower orbit 7g to SEs in higher orbit 7h. SEs are too small to be shown in these orbits. Each 7b line in FIG. 7 represents solar rays from thousands of reflector panels belonging to many SEs.
7c	Solar rays reflected from higher orbit 7h to earth or to SPSA 7p. SEs are too small to be shown in this figure. Each 7c line in FIG. 7 represents solar rays reflected from thousands of reflector panels belonging to many SEs. These solar rays can be aimed at many AAPs on earth or they may be focused on a single AAP at the center of an SPSA disk.
7d	Nature generated whirlwinds.
7e	Earth.
7g	Lower orbit of a nonintersecting-noncoplanar orbital pair.
7h	Higher orbit of a nonintersecting-noncoplanar orbital pair.
7i	Directions of air mass motions induced by SWMS. This will create a whirlwind which can be used to cancel an existing whirlwind 7d.
7j	Direction of air mass motions induced by SWMS. This will create a whirlwind which can be used to increase the strength of an existing whirlwind 7d.
7p	Solar Powered Satellite Airplane (SPSA).
7r	Local region to be warmed by solar energy.
7t	SPSA flight pattern defined by GCS as focal point of thousands of reflecting solar rays. In most cases the SPSA flight path is the same as the common AAP trajectory defined by GCS.
7v	Electricity generating stations: direct solar, wind or hydroelectric.
7w	Greenhouse farms.
7x	Ocean or other wet surfaces to be heated by concentrated solar energy beams. This is done to increase the air mass humidity above 7x.
7y	Increased precipitation by SWMS in southern California
7z	Increased precipitation by SWMS in northern Ethiopia.

APPENDIX: ACRONYMS

AAP Adjusted Aim Point.

GCS Ground Control Station (see FIG. **1**).

LOS Line-Of-Sight.

MMW Millimeter Wave.

RSD Remote Sensing Device (see FIG. **1**).

SE Satellite Engine (See FIG. **2**).

SPSA Solar Powered Satellite Airplane (see FIG. **4**).

SWMS Satellite Weather Modification System (see FIG. **1**).

[SWMS/#]	Invention features relating to Satellite Weather Modification System (SWMS) designs (# = 0, 1, . . . ,5).
[SE/#]	Invention features relating to Satellite Engines (SEs) designs (# = 0, 1, 2, . . . ,6).
[OP/#]	Invention features relating to SEs orbital OPerations (# =0, 1, 2, . . . ,10).
[C/#]	Invention features relating to SEs' energy beam

-continued

	direction Controls (# = 0, 1, 2).
[RSD/#]	Invention features relating to Remote Sensing Devices (RSDs) integration into the SWMS (# = 0, 1, 2).
[GCS/#]	Invention features relating to Ground Control Stations (GCSs) (SEs guidance) designs (# = 0, 1, 2, 3).
[F/#]	Invention features relating to Frequency agile energy beams' frequency and intensity selections (# = 0, 1, . . . ,7).
[W#/#]	Invention features relating to SWMS's basic Weather modification techniques. Four major features are: [W1/0], [W2/0], [W3/O] and [W4/0].
[W1/#]	Invention features relating to modifying global weather conditions (# = 0, 1, . . . ,6).
[W2/#]	Invention features relating to modifying local weather conditions (# = 0, 1, 2).

I claim:

1. Apparatus comprising:

a plurality of satellites, each of said satellites being in a planetary orbit, and each satellite being under remote control and capable of reflecting solar radiation;

a plurality of detectors for monitoring a planetary region, each detector generating at least one signal representative of dynamic or thermodynamic conditions in the monitored region; and

at least one control station responsive to the signals from the detectors and exercising remote control over the satellites for directing solar energy reflected from the satellites towards a plurality of distributed aim points to achieve desired dynamic or thermodynamic properties of the monitored region.

2. Apparatus according to claim **1** wherein the monitored region comprises a land mass.

3. Apparatus according to claim **1** wherein the monitored region comprises a water mass.

4. Apparatus according to claim **1** wherein the monitored region comprises an air mass.

5. Apparatus according to claim **1** wherein the control station comprising means for extrapolating current dynamic or thermodynamic atmospheric values to determine corresponding values at a future time.

6. Apparatus according to claim **1** wherein the control station comprises means for specifying desired dynamic or thermodynamic values at desired locations and desired times.

7. A method comprising:

placing each of a plurality of satellites in a planetary orbit, each satellite being capable of reflecting solar radiation;

selecting a planetary region to be monitored;

detecting dynamic or thermodynamic conditions at a plurality of points in the selected region;

determining an increment of solar radiation needed to substantially conform the detected dynamic or thermodynamic conditions to desired values; and

exercising remote control over the satellites so as to direct solar energy reflected from the satellites towards a plurality of distributed aim points to achieve the determined increment.

8. A method according to claim **7** comprising the step of including a land mass in the selected region.

9. A method according to claim **7** comprising the step of including a water mass in the selected region.

10. A method according to claim **7** comprising the step of including an air mass in the selected region.

11. Apparatus comprising:

at least one million satellites, each of said satellites being in a planetary orbit, and each satellite being under remote control and capable of reflecting solar radiation;

a plurality of detectors for monitoring a planetary region, each detector generating at least one signal representative of dynamic or thermodynamic conditions in the monitored region; and

at least one control station responsive to the signals from the detectors and exercising remote control over the satellites for directing solar energy reflected from the satellites back into space and away from the planet to achieve desired dynamic or thermodynamic properties of the monitored region.

12. Apparatus according to claim **11** wherein:

the number of said satellites is at least one billion.

13. Apparatus according to claim **11** wherein the control station comprising means for extrapolating current dynamic or thermodynamic atmospheric values to determine corresponding values at a future time.

14. Apparatus according to claim **11** wherein the control station comprises means for specifying desired dynamic or thermodynamic values at desired locations and desired times.

15. A method comprising:

placing each of at least one million satellites in a planetary orbit, each satellite being capable of reflecting solar radiation;

selecting a planetary region to be monitored;

detecting dynamic or thermodynamic conditions at a plurality of points in the selected region;

determining a decrement of solar radiation needed to substantially conform the detected dynamic or thermodynamic conditions to desired values; and

exercising remote control over the satellites for directing solar energy reflected from the satellites back into space and away from the planet to achieve the determined decrement.

16. A method according to claim **15** wherein:

the number of said satellites is at least one billion.

[57] ABSTRACT

A system and method for enabling human beings to communicate by way of their monitored brain activity. The brain activity of an individual is monitored and transmitted to a remote location (e.g. by satellite). At the remote location, the monitored brain activity is compared with pre-recorded normalized brain activity curves, waveforms, or patterns to determine if a match or substantial match is found. If such a match is found, then the computer at the remote location determines that the individual was attempting to communicate the word, phrase, or thought corresponding to the matched stored normalized signal.

COMMUNICATION SYSTEM AND METHOD INCLUDING BRAIN WAVE ANALYSIS AND/OR USE OF BRAIN ACTIVITY

This invention relates to a system and method for enabling human beings to communicate with one another by monitoring brain activity. In particular, this invention relates to such a system and method where brain activity of a particular individual is monitored and transmitted in a wireless manner (e.g. via satellite) from the location of the individual to a remote location so that the brain activity can be computer analyzed at the remote location thereby enabling the computer and/or individuals at the remote location to determine what the monitored individual was thinking or wishing to communicate.

In certain embodiments this invention relates to the analysis of brain waves or brain activity, and/or to the remote firing of select brain nodes in order to produce a predetermined effect on an individual.

BACKGROUND OF THE INVENTION

It is known to monitor brain activity by way of electroencephalograph (EEG) methods, magnetoencephalograph (MEG) methods, and the like. For example, see U.S. Pat. Nos. 5,816,247 and 5,325,862, the disclosures of which are both hereby incorporated herein by reference. As discussed in the '247 patent, an EEG may be recorded from a number of pairs of scalp electrodes and processed according to known software. Such software and/or hardware acquires both processed and unprocessed EEG data and may record it on a disk. The records may be replayed and statistics of the on-line measures made on suitable sections placed in categories predefined by a user. This may utilize the form of database of statistical measures of brain activity. Unfortunately, neither the '862 nor the '247 patents disclose or suggest any methods by which humans can communicate with one another by way of monitoring brain activity.

U.S. Pat. No. 5,719,561 discloses a communications device and method, the entire disclosure of the '561 patent hereby being incorporated herein by reference. The '561 patent discusses a method and device for vibromechanical tactile communications adaptable for use by individuals to recognize alpha numeric messages in a language or in other symbols known to them. The '561 patent discusses using a series of sequentially firing vibromechanical stimulators vibrating against a suitably tactile sensitive surface of the wearer (e.g. skin) to induce a phenomenon of illustration of linear continuity. Unfortunately, the '561 patent requires the use of burdensome and complex vibromechanical tactile devices, and is not suitable for long distance communication.

It is a purpose of this invention to address any or all of the above-identified problems in the prior art, as well as other problems which will become apparent to the skilled artisan from the following detailed description of this invention.

SUMMARY OF THE INVENTION

Generally speaking, this invention fulfills the above described needs in the art by providing a method of communicating comprising the steps of:

providing a first human being at a first location;

providing a computer at a second location that is remote from the first location;

providing a satellite;

providing at least one sensor (preferably a plurality—e.g. tens, hundreds, or thousands, with each sensor monitoring the firing of one or more brain nodes or synapse type members) on the first human being;

detecting brain activity of the first human being using the at least one sensor, and transmitting the detected brain activity to the satellite as a signal including brain activity information;

the satellite sending a signal including the brain activity information to the second location;

a receiver at the second location receiving the signal from the satellite and forwarding the brain activity information in the signal to the computer;

comparing the received brain activity information of the first human being with normalized or averaged brain activity information relating to the first human being from memory; and

determining whether the first human being was attempting to communicate particular words, phrases or thoughts, based upon the comparing of the received brain activity information to the information from memory.

In certain embodiments, the invention includes the following step: asking the first human being a plurality of questions and recording brain activity of the first human being responsive to the plurality of questions in the process of developing said normalized or averaged brain activity information relating to the first human being stored in the memory. A database in a memory may include, for each of a plurality (e.g. one hundred or thousands) of individuals, a number of prerecorded files each corresponding to a particular thought, attempt to communicate a word, attempt to communicate a phrase or thought, or mental state. Measured brain activity of a given individual may be compared to files from that database of that individual to determine what the individual is attempting to communicate or what type of mental state the individual is in.

In certain embodiments, the plurality of questions are the same question.

In certain embodiments, the plurality of questions are different questions.

In certain embodiments, the invention includes the step of normalizing or averaging recorded brain activity responsive to a given question or set of questions in developing the normalized or averaged brain activity information relating to the first human being.

It is an object of this invention to enable brain activity of a first human being to be monitored, with the activity being transmitted to a remote location so that individuals and/or a computer at the remote location can determine what the first human being was thinking or intending to communicate. In such a manner, human beings can communicate with one another via monitoring of brain activity, and transmission of the same.

It is another object of this invention to communicate monitored brain activity from one location to another in a wireless manner, such as by IR, RF, or satellite.

It is another object of this invention to provide a system capable of identifying particular nodes in an individual's brain, the firings of which affect characteristics such as appetite, hunger, thirst, communication skills (e.g. which nodes are utilized to communicate certain words such as "yes", "no", or phrases such as "I don't know", "I'm not sure", or numbers such as "one", "two", "ten", "one hundred" and the like), thought processes, depression, and the like). When such nodes are identified, they may be specifically monitored by one or more sensors to analyze behavior or communication or words, phrases, or thoughts. In other embodiments, devices mounted to the person (e.g. underneath the scalp) may be energized in a predetermined manner or sequence to remotely cause particular identified brain node(s) to be fired in order to cause a predetermined feeling or reaction in the individual, such as lack of hunger, lack or depression, lack or thirst, lack of aggression, lack of alzheimer's disease effects, or the like.

Brain node firings are the basis of thought and mind processes of individuals. Certain embodiments of this invention enable such brain firings and behavior to be captured by an external device. It is an object of this invention to utilize a normalization or normalizing curve (or waveform or pattern) based upon monitored brain activity to detect or determine thought processes by the monitored individual. In such a manner, individuals can transmit by satellite what they are thinking or intending to think via their monitored brain activity, without the need to talk or write down information.

Each individual has a distinct pattern of brain node firings or brain activity. Each person is believed to be different in this regard. Thus, a separate brain activity file may be stored in a memory for each individual, and analyzed or compared to received brain activity from the monitored individual in order to determine what that individual is thinking or attempting to communicate.

It is an object of this invention to utilize brain monitoring and transmission of monitored brain activity for lie detection and/or human communication.

It is another object of this invention to formulate or build-up a file for each individual based upon patterns recorded in response to that individual answering or responding to numerous predetermined questions with known intended responses. Subsequently, monitored brain activity from that individual may then be compared to information stored corresponding to that individual to determine whether the individual is lying or what the individual is intending to communicate in the monitored brain activity. The higher the level of detail of the file, the higher the level of potential communication by certain embodiments of this invention.

At least one sensor on the scalp or skin in certain embodiments provides signals representative of physiological activity generated in the brain of a monitored individual. A data acquisition device receives the signals representative of the physiological activity generated in the monitored brain, and transforms the signals into a pattern or curve corresponding to the monitored brain activity. This is then transmitted (e.g. by satellite) to a computer located at a remote location, with the monitored brain activity pattern or curve being stored in a memory at the remote location. The computer then causes the received pattern or curve information to be compared with stored brain activity pattern information relating to the monitored individual in order to determine (a) whether the monitored individual is lying in response to a particular question, or (b) what the monitored individual is communicating or attempting to communicate.

Another object of this invention is to utilize normalization curves representative of received brain activity patterns from the monitored individual, and to compare the received normalized data with normalized brain activity pattern or curve data stored in memory relating to that individual. The use of normalization curves in one or both of the individual's file and received brain activity improves reliability, accuracy, and efficiency.

In certain embodiments of this invention, the computer located at the remote location includes a neural network suitably programmed in accordance with known neural network techniques, for the purpose of receiving the monitored brain activity signals, transforming the signals into useful forms, training and testing the neural network to distinguish particular forms and patterns of physiological activity generated in the brain of the monitored individual, and/or comparing the received monitored brain activity information with stored information relating to that individual in order to determine what the individual is attempting to communicate.

This invention further fulfills the above described needs in the art by providing a method of affecting a mental or physiological state of an individual, the method comprising the steps of:

providing at least one firing device capable of being energized on an individual; and

energizing the firing device to cause the firing device to cause a particular or group of brain nodes to be fired in the individual in order to affect the mental or physiological state of the individual.

In certain embodiments, the method including the step of providing the at least one firing device on or under the scalp of the individual in proximity of the brain of the individual.

In certain embodiments, the method including the step of identifying at least one brain node related to the mental or physiological state intended to be affected, targeting the identified brain node, and energizing the firing device or devices to cause the identified node to be fired in order to affect the mental or physiological state of the individual.

In certain embodiments, the method is utilized to cause the individual to be one of less hungry, less thirsty, less anxious, and less depressed.

In certain embodiments, the remote node firing devices are electrically energized and generate electromagnetic waves which cause a plurality of brain nodes to be fired.

This invention will now be described with respect to certain embodiments thereof, along with reference to the accompanying illustrations.

IN THE DRAWINGS

FIG. **1** is a block diagram illustrating the system and method according to a first embodiment of this invention.

FIG. **2** is a block diagram illustrating the neural network inclusive computer of the FIG. **1** embodiment of this invention.

FIGS. **3**(*a*)–**3**(*f*) are exemplary graphs of monitored brain activity of different individuals, with, for example, FIG. **3**(*a*) illustrating monitored brain activity of a particular individual who is attempting to communicate the word "no" and FIG. **3**(*b*) illustrating monitored brain activity of the same individual when that individual is attempting to communicate the word "yes."

DETAILED DESCRIPTION OF CERTAIN EMBODIMENTS OF THIS INVENTION

Referring now more particularly to the accompanying drawings in which like reference numerals indicate like parts throughout the several views.

There are significant individual differences in electrical and magnetic activity in the brain. Brain node or synapse firings are chemically and/or electrically caused and/or related. Some characteristics of brain activity may be relatively stable when measured from day to day. Brain responses to sensory stimulation (e.g. visual, audible, olfactory, gustatory, etc.) as well as higher order cognitive processing (e.g. decision-making or thought/word communication), can be examined in great detail using a variety of recording procedures. A recording of brain electrical activity is called an electroencephalograph (EEG), and a comparable record of magnetic activity is called a magnetoencephalogram (MEG). When human sensory systems are stimulated by a particular event (a given sound or optical effect) or when a human wishes to communicate a particular word or phrase (e.g. the word "yes" or the word "no"), there is a predictable sequence of processing that occurs in the brain. This processing generates an event related potential that can be recorded from the scalp beginning shortly after the onset of the stimulation, and lasting for approximately 0.5–4 seconds after the stimulation. These potentials can be repeatedly generated from individuals given the same stimulus or wishing to communicate the same word or phrase. In certain embodiments of this invention, brain activity may be repeatedly sampled, and response patterns averaged by way of a normalization curve or the like. Comparable recordings of averaged or normalized magnetic activity may be referred to as evoked fields. Neuroelectric and neuormagnetic recordings are subsets of general measurings referred to as bioelectric and biomagnetic measures. These measures refer to recordings which may be made from different types of tissue including neural, muscle, heart, etc. For example, EEG, evoked potentials (EP), MEG, position emission tomography (PET) of glucose, or single photon emission computed tomography (SPECT) may be used to monitor brain activity in different embodiments of this invention.

Event related potentials have been shown to be stable and unique to individuals. See U.S. Pat. No. 5,325,862, which is incorporated herein by reference. Although the actual shape of such potentials varies considerably from individual to individual, there is stability within individuals over time for individual waveforms. Sources of these potentials and variations thereof include individual differences in brain anatomy and differences in the way in which information is processed by each individual. Thus, it is feasible herein to utilize monitored brain waveforms for the purpose of determining whether an individual is lying or not, or what word or phrase a particular individual is attempting to communicate (without the need for writing information down or speaking).

Thus, evoked fields and/or event related potentials can be utilized as classifiers for several purposes. For example, because these potentials and/or fields are relatively unique to individuals, an individual's evoked field or event related potential (or brainprint) can be utilized to determine what thoughts an individual is communicating or attempting to communicate given knowledge of the identification of that individual and previously recorded patterns associated with that individual communicating predetermined words, phrases or thoughts. Because there is a remarkable degree of stability in individual waveforms of a person over time, it is possible to identify changes in individual event related potentials and evoked field patterns which can be utilized to determine when an individual is lying, or impaired in any way.

There are numerous neural networks in the brain, these networks having complex inner connections and non-linear response patterns. Relationships between the latencies and amplitudes of event related potentials and evoked field waveform features have become well understood. In addition, there are many individual variations in waveform morphology. Computing techniques modeled after brain neural functions are known in the art. They are typically referred to as neural network analysis techniques or computers. Neural network analysis computing technology offers a method for finding complex, non-linear relationships in large data sets, even when the nature of the relationships is not known in advance. Neural network technology is implemented sometimes using computer software programs, but may also be hardware implemented. Neural network theory, and detailed descriptions of specific techniques, are available in numerous books and articles set forth in the aforesaid '862 patent, as well as in, for example, any of U.S. Pat. Nos. 5,136,687; 5,059,814; 5,461,699; 5,737,485; 5,224,203; and 5,640,493, the entire disclosures of which are all hereby incorporated herein by reference. Such neural computing systems have a capability to learn features of data sets and classify same into either unknown or predetermined categories. A variety of neural network techniques may be utilized to classify event related potentials, evoke fields, or any other type of pattern corresponding to monitored brain behavior. In most neural networks, input values are adjusted through a series of layers by a series of transforms and weighted so that output categories are correctly predicted. Thus, a neural computing system herein may be utilized to receive monitored brain activity and based upon predetermined stored and/or learned information, determine based upon the received information what word, phrase, or thoughts the monitored individual is attempting to communicate. In such a manner, the monitoring of brain activity may be utilized to allow individuals to communicate from one location to another, with the neural computer or any other type of computer analyzing the monitored brain information (e.g. via comparison with previously recorded brain activity of that person) and outputting information indicative of the word, phrase, or thoughts which the monitored individual is attempting to communicate.

FIG. **1** illustrates a particular monitored individual **3** according to an embodiment of this invention. Individual **3** includes a head **5**. As illustrated, sensors **7** may be attached or otherwise disposed adjacent to the scalp or skin of the individual **3**. Sensors **7** detect and monitor brain activity of individual **3**. Sensors **7** can detect event related potentials and/or event related fields (i.e. ERPs or ERFs). Optionally, sensor **7** may be utilized to detect any other type of "brainprint" indicative of brain activity of individual **3**.

The monitored "brainprint" of individual **3** is forwarded to a small transmitter **9** which is preferably embedded in the skin of individual **3**, or in close proximity to individual **3**. Transmitter **9** causes the monitored "brainprint" information detected by sensor **7** to be transmitted by way of antenna **11** as wireless signals **13**. In certain embodiments of this invention, signals **13** propagate through atmospheric free space in the form of uplink satellite signals toward satellite **15**. Satellite **15** receives signals **13** and then redirects those signals back toward Earth as signals **17** which include information therein (analog or digital) indicative of the monitored brain activity of individual **3**. Signals **17** are received by antenna **19**. Antenna **19** and individual **3** are both preferably located on Earth at different locations. In certain embodiments, antenna **19** is located at a location remote from individual **3**. For example, individual **3**, sensor **7**, transmitter **9**, and antenna **11** may all be located in Europe while receiving antenna **19** and computer **21** may be located in the United States.

FIG. **1** illustrates both a digital embodiment **23** and an analog embodiment **25** of receiving systems. Either may be utilized. When signals **17** include digital information, they are received by antenna **19** and forwarded to tuner **27**. The signals are processed through equalizer **29**, demodulator **31**, parallel to serial converter **33**, deinterleaver **35**, decoder **37**, descrambler **39**, digital estimator **41**, and finally to neural network analysis or other type of computer **21**. Monitored firings of brain nodes may be broken down into digital form (e.g. the firing of a node is equivalent to a "**1**" and nonfiring to a "0"). These 1s and 0s, which are digital, may be modulated onto a carrier and then transmitted to the satellite so that the monitored brain activity in the signal is in digital form. When the computer receives this monitored signal from the satellite, the demodulating system analyzes the received digital information (e.g. 1s and 0s) which is indicative of the firing of select brain nodes of the monitored individual. These digital signals may be transformed, in certain embodiments, into analog form similar to the illustrations of FIG. **3**, or alternatively may be kept in digital form and compared with prestored digital signals to determine what the monitored person was intending to communicate.

In analog embodiments, signal **17** is received by antenna **19**, and the information forwarded to tuner **27**, amplifier **43**, and the analog information inclusive signal **45** is forwarded to computer **21**. In analog embodiments, the signals received by the monitoring sensors are in the form of waves similar to those shown in FIG. **3** herein.

FIG. **2** is a block diagram of computer **21** in certain embodiments of this invention. The input thereto may be in either analog or digital form. Computer **21** includes processor **51**, RAM **53**, comparing device **55**, and memory **57** for storing a plurality of files or patterns of measured brain activity or responses of particular individuals. For example, memory or storage **57** may include one file for individual X which includes hundreds of monitored brain activity (e.g. ERPs or ERFs) that were measured when individual X was attempting to communicate the word "no." Another file in storage or memory **57** may have stored therein hundreds or thousands of monitored brain patterns or activities of individual X when individual X was attempting to communicate the word "yes." Storage or memory **57** may also include similar files for individual X including patterns which were measured when the individual was attempting to communicate different words or phrases. Each of these files may have a normalized curve, waveform or pattern formed or developed for each word, phrase, or thought for each individual, based upon all of the recorded patterns or curves for that word, phrase, or thought (e.g. 1,000 such recordings for the phrase "help me," and 1,000 for the phrase "I've been caught." Memory **57** further includes in certain embodiments many different files for many different individuals, all including files for each individual's past communicating of particular words, phrases, or thoughts.

Normalized curves or patterns corresponding to each individual's attempt to communicate a particular word, thought, or a pattern may be stored in storage or memory **57**. Thus, for individual X attempting to communicate the word "no", a normalized curve, waveform, or a pattern may be stored in memory **57** indicative or such a communication. Likewise, a normalized curve, waveform, or pattern may be stored in memory **57** for individual Y attempting to communicate the word "no" and another distinct normalized curve, waveform, or pattern may be stored in memory **57** for individual Y attempting to communicate the word "yes." In a similar manner, a normalized curve, waveform or pattern may be stored in memory **57** for individual Y attempting to communicate the phrase "I don't know" or "I'm not sure." Thus, if one hundred different human beings have files in memory **57** corresponding to each of these individual's attempt to communicate the phrase "I don't know", then one hundred different normalized waveforms, curves or patterns would be stored in memory **57**, each corresponding to a particular individual. A normalized curve, waveform, or pattern may be developed by repeatedly asking an individual tens, hundreds, or thousands of times a particular question or group of questions which evoke a known response such as "I don't know," or "no" or "yes." Each time the response is made, a curve, waveform, or a pattern is recorded. After tens, hundreds, or even thousands of these patterns have been recorded, a normalized curve, waveform or pattern is formed based upon same so as to be indicative of that particular individual's attempt to communicate the phrase. In a similar manner, if it is desired to store normalized curves, waveforms, or patterns for ten different words, phrases or thoughts communicated by a particular individual, then a normalized curve, waveform, or pattern is developed for each of the different ten items so that ten different normalized curves, waveforms or patterns are stored in memory **57** for that individual and classified accordingly. Thus, when computer **21** receives signals indicating brain activity from that monitored individual, the received signals are compared by device **55** to the ten different normalized signals in memory **57** in order to determine what the individual is attempting to communicate.

FIGS. **3**(*a*)–**3**(*f*) illustrate different normalized curves which may be stored in memory **57**. FIG. **3**(*a*) shows a normalized curve indicative of individual "Joe" attempting to communicate the word "no." FIG. **3**(*b*) shows a normalized curve indicative of individual "Joe" attempting to communicate the word "yes." FIG. **3**(*c*) shows a normalized curve indicative of another individual "Steve" attempting to communicate the word "no", while FIG. **3**(*d*) shows a normalized curve indicative of individual "Steve" attempting to communicate the word "yes." Finally, FIG. **3**(*e*) shows a normalized curve indicative of still another individual "Anita" attempting to communicate the word "no", while FIG. **3**(*f*) illustrates a normalized curve of "Anita" attempting to communicate the word "yes."

Thus, if computer **21** receives a signal including monitored brain information identified as being from individual "Steve", then computer **21** causes the received signal to be compared by device **55** with the normalized curves or waveforms shown in FIGS. **3**(*c*) and **3**(*d*) and all others normalized stored signals of "Steve." If a match or a close match is found between the received monitored signal and the normalized curve of FIG. **3**(*c*), then the computer determines that "Steve" was attempting to communicate the word "no." Meanwhile, if no match is found with the normalized curve of FIG. **3**(*c*), but a match or a substantial match is found with regard to the normalized curve or waveform of FIG. **3**(*d*), then the computer determines that "Steve" was attempting to communicate the word "yes." If no match is found between the received "Steve" signal and any normalized curve or waveform of either FIG. **3**(*c*) or FIG. **3**(*d*), or with any other normalized curve stored in memory **57** corresponding to "Steve", then the computer determines that it is unclear what "Steve" was attempting to communicate.

Thus, different embodiments of this invention may be utilized to help individuals communicate with one another without having to send faxes, make telephone calls, speak, or the like. For instance, military personnel located in the Middle East or Europe can communicate with superiors in the Pentagon, simply by use of monitored brain activity being transmitted by satellite to the Pentagon. Alternatively, a special operations individual (e.g. a spy) located in Europe could be asked a question by way of a telephone call, fax, or the like, and that individual can respond to that question simply by thinking the answer so that that individual's monitored brain activity which is transmitted back to the United States can be analyzed to determine the individual's response. In further embodiments of this invention, twoway human communication is possible, provided that human beings at both locations have equipment capable of analyzing and monitoring received monitored brain activity. In such a manner, individuals at two remote locations may communicate with one another without either individual having to speak a word, write anything down, or the like.

In other embodiments, devices mounted to the person (e.g. underneath the scalp) may be energized in a predetermined manner or sequence to remotely cause particular identified brain node(s) to be fired in order to cause a predetermined feeling or reaction in the individual, such as lack of hunger, lack or depression, lack or thirst, lack of aggression, lack of alzheimer's disease effects, or the like. In an example of such an embodiment, the sensors may be replaced with remote firing devices. The computer may cause satellite signals to be sent to a receiver on or proximate an individual, which receiver forwards instructions to the remote firing devices that are mounted, e.g. under the scalp of the individual, in order to selectively cause same to fire or be energized. Such energizing of the device(s) under or near the scalp in a predetermined manner tend to cause identified brain nodes to fire a predetermined number of times. This is useful, for example, in the following scenarios. For example, the system can be used to identify which brain node(s) in a particular individual are typically fired causing that individual to not be hungry. If that individual has an eating disorder or problems with obesity, then the firing devices can be remotely energized thereby causing the identified brain node(s) to be fired at predetermined or random times in order to cause the individual to not be hungry (even if the individual has not eaten for several hours or several days).

In a similar manner, brain nodes which cause an individual to be jovial or not depressed can be identified, and caused to be remotely fired by the computer and firing devices **7** mounted under the scalp in a predetermined manner or sequence(s) in order to minimize or prevent depression of the individual. This may eliminate the need for drugs such a Prozac. Alternatively, such drug(s) may be administered after such remote node firings, and the nodes at issue thereafter being monitored as discussed above and a biofeedback being performed to determine the effectiveness of the drug(s) or alternatively to enable a system to be utilized combining drug treatment with remote node firings to more effectively prevent or minimize depression of the individual. Thus, the biofeedback may enable the identified nodes to be fired by the firing devices and/or drug treatment at the proper level to most efficiently treat the disease, illness or state. This invention, including remote firings and/or monitoring, is not limited to these examples, and its potential uses are almost endless. Brain node firings can be remotely controlled in a predetermined manner or sequence (s) (even random or sequential) to reduce, minimize, or eliminate undesirable behavior or mental characteristics. This may eliminate or reduce the need for burdensome drug treatments and the like. Brain node firings of a normal person, or of a particular person in a given mental or physical state, may be monitored and the brain activity stored and analyzed in the computer **21** memory. This stored brain activity may then be caused by remotely causing the firing devices to cause particular brain node(s) to be fired at given times or intervals in a predetermined manner or sequence. The computer may be programmed to instruct the brain sensors and/or firing devices to identify which brain nodes are responsible for which types of physical or mental behavior, and then the computer transmits firing instructions to the firing devices for those nodes to cause them to be fired in a predetermined manner to effect such physical or mental behavior.

Once given the above disclosure, many other features, modifications, and improvements will become apparent to the skilled artisan. Such other features, modifications, and improvements are, therefore, considered to be a part of this invention, the scope of which is to be determined by the following claims.

I claim:

1. A method of communicating comprising the steps of:

providing a first human being at a first location;

providing a computer at a second location that is remote from the first location;

providing a satellite;

providing at least one sensor on the first human being;

detecting brain activity of the first human being using the at least one sensor, and transmitting the detected brain activity to the satellite as a signal including brain activity information;

the satellite sending a signal including the brain activity information to the second location;

a receiver at the second location receiving the signal from the satellite and forwarding the brain activity information in the signal to the computer;

comparing the received brain activity information of the first human being with normalized or averaged brain activity information relating to the first human being from memory; and

determining whether the first human being was attempting to communicate particular words, phrases or thoughts, based upon the comparing of the received brain activity information to the information from memory.

2. The method of claim **1**, further including the following steps:

asking the first human being a plurality of questions and recording brain activity of the first human being responsive to the plurality of questions in the process of developing said normalized or averaged brain activity information relating to the first human being stored in the memory.

3. The method of claim **2**, wherein the plurality of questions are the same question.

4. The method of claim **2**, wherein the plurality of questions are different questions.

5. The method of claim **2**, further comprising the step of normalizing or averaging recorded brain activity responsive to a given question or set of questions in developing the normalized or averaged brain activity information relating to the first human being.

6. A method of communicating words from a first location to a second location, the method comprising the steps of:

providing a first human being at the first location;

providing a computer at the second location that is remote from the first location;

providing at least one sensor on the first human being;

detecting brain activity of the first human being using the at least one sensor wherein the brain activity is indicative of words to be communicated by the first human being, and forwarding the detected brain activity indicative of words to be communicated to the computer at the second location;

comparing the received brain activity of the first human being indicative of words to be communicated with normalized or averaged brain activity information relating to the first human being from memory; and

determining words being communicated by the first human being based upon the comparing of the received brain activity information to the information from memory.

7. The method of claim **6**, further including asking the first human being a plurality of questions and recording brain activity of the first human being responsive to the plurality of questions in a process of developing the normalized or averaged brain activity information relating to the first human being.

8. The method of claim **6**, further comprising the step of the computer outputting words determined in said determining step to a second human being so that words thought or stated by the first human being are communicated by the first human being to the second human being via the computer.

[57] **ABSTRACT**

In human subjects, sensory resonances can be excited by subliminal atmospheric acoustic pulses that are tuned to the resonance frequency. The ½ Hz sensory resonance affects the autonomic nervous system and may cause relaxation, drowsiness, or sexual excitement, depending on the precise acoustic frequency near ½ Hz used. The effects of the 2.5 Hz resonance include slowing of certain cortical processes, sleepiness, and disorientation. For these effects to occur, the acoustic intensity must lie in a certain deeply subliminal range. Suitable apparatus consists of a portable battery-powered source of weak subaudio acoustic radiation. The method and apparatus can be used by the general public as an aid to relaxation, sleep, or sexual arousal, and clinically for the control and perhaps treatment of insomnia, tremors, epileptic seizures, and anxiety disorders. There is further application as a nonlethal weapon that can be used in law enforcement standoff situations, for causing drowsiness and disorientation in targeted subjects. It is then preferable to use venting acoustic monopoles in the form of a device that inhales and exhales air with subaudio frequency.

SUBLIMINAL ACOUSTIC MANIPULATION OF NERVOUS SYSTEMS

BACKGROUND OF THE INVENTION

The central nervous system can be manipulated via sensory pathways. Of interest here is a resonance method wherein periodic sensory stimulation evokes a physiological response that peaks at certain stimulus frequencies. This occurs for instance when rocking a baby, which typically provides relaxation at frequencies near ½ Hz. The peaking of the physiological response versus frequency suggests that one is dealing here with a resonance mechanism, wherein the periodic sensory signals evoke an excitation of oscillatory modes in certain neural circuits. The sensory pathway involved in the rocking example is the vestibular nerve. However, a similar relaxing response at much the same frequencies can be obtained by gently stroking a child's hair, or by administering weak heat pulses to the skin, as discussed in U.S. Pat. No. 5,800,481, Sep. 1, 1998. These three types of stimulation involve different sensory modalities, but the similarity in responses and effective frequencies suggests that the resonant neural circuitry is the same. Apparently, the resonance can be excited either via vestibular pathways or via cutaneous sensory pathways that carry tactile or temperature information.

Near 2.5 Hz another sensory resonance has been found that can be excited by weak heat pulses induced in the skin, as discussed in U.S. Pat. No. 5,800,481, Sep. 1, 1998. This sensory resonance brings on a slowing of certain cortical functions, as indicated by a pronounced increase in the time needed to silently count backward from 100 to 70 with the eyes closed. The effect is sharply dependent on frequency, as shown by a response peak a mere 0.13 Hz wide. The thermally excited 2.5 Hz resonance was found to also cause sleepiness, and after long exposure, dizziness and disorientation.

Other, more obscure types of stimulation in the form of weak magnetic fields or weak external electric fields can also cause the excitation of sensory resonances, as

SUMMARY OF THE INVENTION

Experiments have shown that atmospheric acoustic stimulation of deeply subliminal intensity can excite in a human subject the sensory resonances near ½ Hz and 2.5 Hz. The ½ Hz resonance is characterized by ptosis of the eyelids, relaxation, drowsiness, a tonic smile, tenseness, or sexual excitement, depending on the precise acoustic frequency near ½ Hz that is used. The observable effects of the 2.5 Hz resonance include a slowing of certain cortical functions, sleepiness, and, after long exposure, dizziness and disorientation. The finding that these sensory resonances can be excited by atmospheric acoustic signals of deeply subliminal intensity opens the way to an apparatus and method for acoustic manipulation of a subject's nervous system, wherein weak acoustic pulses are induced in the atmosphere at the subject's ears, and the pulse frequency is tuned to the resonance frequency of the selected sensory resonance. The method can be used by the general public for control of insomnia and anxiety, and for facilitation of relaxation and sexual arousal. Clinical use of the method includes the control and perhaps a treatment of anxiety disorders, tremors, and seizures. A suitable embodiment for these applications is a small portable battery-powered subaudio acoustic radiator which can be tuned to the resonance frequency of the selected sensory resonance.

There is an embodiment suitable for law enforcement operations in which a subject's nervous system is manipulated from a considerable distance, as in a standoff situation. Subliminal subaudio acoustic pulses at the subject's location may then be induced by acoustic waves radiating from a venting acoustic monopole, or by a pulsed air jet, especially when aimed at the subject or at another material surface, where the jet velocity fluctuations are wholly or partly converted into static pressure fluctuations.

The described physiological effects occur only if the intensity of the acoustic stimulation falls in a certain range, called the effective intensity window. This window has been measured in exploratory fashion for the 2.5 Hz resonance.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** illustrates a preferred embodiment wherein a modulated air jet is used for inducing subliminal acoustic pulses in the atmosphere at the subject's ears, for the purpose of manipulating the subject's nervous system.

FIG. **2** shows an embodiment in which a pulsed air jet is produced by modulating the flow from a fan by a cylindrical sheet valve that is driven by a voice coil.

FIG. **3** shows schematically an acoustic monopole operated by a solenoid valve.

FIG. **4** shows the circuit of a simple generator for producing voltage pulses that drive a piezoelectric speaker.

FIG. **5** depicts a portable battery-powered device that contains the circuit and the piezoelectric speaker of FIG. **4**.

FIG. **6** shows schematically a generator for chaotic pulses.

FIG. **7** depicts a circuit for generating a complex wave.

FIG. **8** illustrates an application in a law enforcement standoff situation.

FIG. **9** contains experimental data that show excitation of the sensory resonance near 2.5 Hz, and the effective intensity window.

FIG. **10** depicts experimental data showing that the sensory excitation occurs via the ear canal.

FIG. **11** shows the buildup of the physiological response to the acoustic stimulation.

FIG. **12** shows schematically an acoustic monopole operated by a rotating valve.

DETAILED DESCRIPTION OF THE INVENTION

It has been found in our laboratory that deeply subliminal atmospheric acoustic pulses with frequency near ½ Hz can evoke in a human subject a nervous system response that includes ptosis of the eyelids, relaxation, drowsiness, the feeling of pressure at a centered spot on the brow, seeing moving patterns of dark purple and greenish yellow with the eyes closed, a soft warm feeling in the stomach, a tonic smile, a "knot" in the stomach, sudden loose stool, and sexual excitement, depending on the precise acoustic frequency used. These responses show that this sensory resonance involves the autonomic nervous system.

The sharp peaking of the physiological effects with frequency is suggestive of a resonance mechanism, wherein the acoustic stimulation, although subliminal, causes excitation of a resonance in certain neural circuits. Since the frequencies and responses are similar to those for the ½ Hz sensory resonance discussed in the Background Section, it appears that the resonance excited by the described acoustic stimulation is indeed the ½ Hz sensory resonance. It has been found that the 2.5 Hz sensory resonance can be excited acoustically as well. This sensory resonance causes the slowing of certain cortical processes, sleepiness, and eventually dizziness and disorientation.

One can avoid the described physiological responses by wearing snugly fitting ear plugs. This shows that the excitation occurs via the external ear canal, so that the stimulation proceeds either through the auditory nerve or the vestibular nerve. Frequencies near ½ Hz or 2.5 Hz are far too low for stimulating the cochlear apparatus, but they are within the response range of hair cells in the vestibular end organ. Also, there exists a low-frequency acoustic path to the vestibular end organ by virtue of the ductus reuniens which provides a fluid connection between the cochlea and the vestibular organ. The narrow duct severely attenuates acoustic signals and acts as a low pass filter with a very low cutoff frequency. Subaudio acoustic signals, i.e., acoustic signals with frequencies up to 15 Hz, may perhaps penetrate to the vestibular organ with sufficient strength for stimulating the exquisitely sensitive vestibular hair cells.

For the ½ Hz and 2.5 Hz resonances, the described physiological responses are observed only if the acoustic intensity lies in a certain interval, called the effective intensity window. The acoustic intensity levels in this window are far below the human auditory threshold, so that exposed subjects do not sense the acoustic pulses in any other way than through the mentioned physiological effects. The upper limit of the effective intensity window is believed to be due to nuisance-guarding neural circuitry that blocks repeditive nuisance signals from higher processing.

The acoustic signals used for the excitation of sensory resonances have the nature of pulses. The pulses may be square, trapezoid, or triangle, or rounded versions of these shapes. However, depending on the pulse frequency, strong harmonics with frequencies in the audible range could stimulate the cochlear apparatus. This may be avoided by using sine waves or appropriately rounded other waves with low harmonic content.

The acoustic pulses occur in the atmosphere air; even when administered with earphones, the pulses at the subject's ear constitute pressure and flow pulses in the local atmospheric air.

The resonance frequencies of the ½ Hz and 2.5 Hz sensory resonances lie respectively near ½ and 2.5 Hz. The different physiological effects mentioned occur at slightly different frequencies. Thus, one can tune for drowsiness or sexual excitement, as desired. The precise resonance frequency is also expected to depend slightly on the subject and the state of the nervous and endocrine systems, but it can be measured readily by tuning the acoustic pulse frequency for maximum physiological effect. Besides the resonances near ½ and 2.5 Hz, other sensory resonances may perhaps be found, and those with resonance frequencies below 15 Hz are expected to be excitable acoustically via the vestibular nerve, since the vestibular hair cells are sensitive in this frequency range.

The finding that deeply subliminal subaudio acoustic stimulation can influence the central nervous system suggests a method and apparatus for manipulating the nervous system of a subject by inducing subliminal atmospheric acoustic pulses of subaudio frequency at the subject's ears. In doing so, one may in addition exploit the sensory resonance mechanism, but there are important applications where this is not done. For example, the subliminal acoustic manipulation of the nervous system may be used clinically for the control of tremors and seizures, by detuning the pathological oscillatory activity of neural circuits that occurs in these disorders. This may be done by choosing an acoustic frequency that is slightly different from the frequency of the pathological oscillation. The evoked neural signals then cause phase shifts which may diminish or quench the oscillation. Exploitation of the resonance mechanism by tuning the acoustic signals to the resonance frequency of a selected sensory resonance affords other forms of manipulation, such as control of insomnia and anxiety, or facilitation of sexual arousal.

For both types of manipulation, the required subliminal subaudio acoustic pulses may be induced at one or both of the subject's ears by earphones with a proper low-frequency response, acoustic waves generated by an acoustic source and propagated through the atmosphere, or by a pulsed jet of gas (which may be air), preferably directed at a material surface open to the atmosphere, such as a wall or the subject's skin or clothing. In the area of impact, especially where the surface is oriented substantially perpendicular to the jet, atmospheric pressure pulses are then generated by virtue of the ram effect, wherein flow velocity fluctuations are wholly or partly converted into static pressure fluctuations. If the material surface on which the jet impinges includes the subject's ears, then these pressure pulses cause direct stimulation of the subject, but the pulses also propagate through the atmosphere to the subject's ears by virtue of acoustic wave propagation along accessible paths.

The induction of atmospheric acoustic pulses by a pulsed air jet proceeding in the atmosphere and directed at a subject is shown in FIG. **1**, where a blower **1**, labeled "FAN", produces an air jet **2** that is directed at a subject **3**. The fan is powered by a power supply **4**, labelled "SUPPLY". At the fan, the supply voltage is modulated in pulsed fashion by a relay **5** controlled by the generator **6**, labelled "GENERATOR", through voltage pulses **7** supplied to electromagnet windings **8**. A user can adjust the frequency of the pulses with the tuning control **9**. The pulsing of the voltage supplied to the fan causes the momentum flux **10** of the air jet to be modulated in a pulsed manner. Upon impinging on a material surface such as the skin of the subject **3**, the pulsed jet induces acoustic pressure pulses at the ears **11** of the subject. The atmospheric acoustic effect of the jet is complicated by the fact that the region of the fan inlet undergoes a fluctuation of static pressure as the result of the modulation of jet momentum flux. There thus are two distinct acoustic monopoles, one at the fan inlet and the other in the area of impact of the jet on the material surface. The monopoles radiate with a phase difference that is determined by the jet velocity, the modulation frequency, and the distance between fan and impact area. The resulting sound pressure at the subject's ears can be analyzed with retarded potentials as discussed for instance by Morse and Feshbach (1953). Even a jet which does not impinge on a material surface radiates by virtue of the acoustic monopole at the fan inlet.

When skin of the subject is exposed to gas flow of the jet, or to the flow of atmospheric air entrained by the jet, the flow will fluctuate in pulsed fashion, so that a periodic heat flux occurs by convective transport and evaporation of sweat. The resulting periodic fluctuation of the skin temperature can excite a sensory resonance, as discussed in U.S. Pat. No. 5,800,481, Sep. 1, 1998. Hence, the apparatus of FIG. **1** can cause excitation of a sensory resonance via two separate sensory pathways, viz., the vestibular nerve and the afferents from cutaneous temperature receptors. The strength of the thermal stimulation depends on the skin area and type of skin exposed to the fluctuating flow. The face is particularly sensitive, especially the lips. The two-channel excitation of sensory resonances needs further investigation. In any particular situation, the vestibular channel can be blocked by using earplugs.

An air jet with pulsed momentum flux can also be obtained as illustrated in FIG. **2**. Shown is a fan **1**, labelled "FAN", which discharges into manifold **12**. The air flow in the manifold can be partially obstructed by a sheet valve **13** in the form of a perforated cylindrical sheet. The sheet valve carries a voice coil **14** which is situated in the field of a permanent magnet **15**, in the manner of conventional electromagnetic loudspeakers. When no current flows through the voice coil, the sheet valve is held in equilibrium position by springs **16**. In this position, the perforation **17** in the sheet is lined up with the flow passage allowing essentially unimpeded flow through the manifold and out the exit **18**, such as to form a jet **19** in the atmosphere. Sending a current pulse through the voice coil **14** causes the sheet valve to be displayed in the axial direction, thereby partially obstructing the air flow through the manifold. Owing to the low inertia of the sheet valve, the arrangement allows efficient pulse modulation of the jet momentum flux.

A somewhat different modulation system can be obtained with a rotating cylindrical sheet valve that has one or more holes along its periphery, and which is adjacent to a stationary cylindrical shroud that has corresponding holes, so that rotation of the valve causes modulation of the air flow through the holes. The valve is rotated by a stepper motor driven by voltage pulses. The latter are obtained from a generator that is controlled by a tuner.

One can also use direct acoustic wave propagation for inducing the required atmospheric acoustic pulses. It is then advantageous to employ as the source of the waves an acoustic monopole, since for these the acoustic pressure does not fall off as fast with increasing distance as for dipoles. Moreover, at the very low frequencies involved, acoustic pressure shorting across a conventional loudspeaker baffle is very severe. A sealed loudspeaker mounted in an airtight box eliminates this pressure shorting, and radiates acoustic waves with a relatively large monopole component.

An acoustic monopole may also be produced by having a source of pressurized gas vent through an orifice into the atmosphere in a pulsed fashion. The gas may be air. Alternatively, one may have a source of low-pressure air inhale atmospheric air through an orifice in pulsed fashion. These actions are easily achieved by an oscillating or rotating valve. For purposes of discussion it is convenient to introduce the concept of gaseous flux through the orifice, defined as the integral of the normal flow velocity component over an imagined surface that tightly caps the orifice, the normal component being perpendicular to the local surface element, and reckoned positive if the flow is directed into the ambient atmosphere. The gaseous flux has the dimension of m^3/s. For the case with a source of pressurized gas, the gaseous flux is positive and due to gas venting to the atmosphere. For the case with a source of vacuum, the gaseous flux is negative and due to atmospheric air entering the orifice. The strength of the acoustic monopole is expressed as the amplitude of the gaseous flux fluctuation, amplitude being defined as half the peak-to-peak variation. The concept of gaseous flux allows a unified discussion of venting acoustic monopoles that use a source of pressurized gas or a source of vacuum, or both.

The source of pressurized air could be a cylinder with pressurized gas, such as a CO_2 cartridge. For personal use, such a cartridge may last a long time because only very small acoustic monopole strengths are needed for the induction of the required weak acoustic signals. For long term and long range operation, the exhaust port of an air pump may serve as a source of pressurized air, and the intake port could be used as a source of vacuum.

A simple venting acoustic monopole is shown in FIG. **12**, where the source **63** of pressurized gas, which may be air, is connected to a conduit **69** which has an orifice **65** that is open to the atmosphere. A rotating valve **66** labelled "VALVE" controls the gaseous flux through the orifice. The valve is rotated by a stepper motor **67** labelled "MOTOR", driven by voltage pulses from the generator **68** labelled "GENERATOR". The motor speed is determined by the frequency of the voltage pulses. This frequency can be selected by the tuner **70**, which therefore controls the frequency of the acoustic pulses emited by the orifice **65**. For the simple orifice shown, boundary layer separation may occur in the outflow, so that the air pulses emerge in the form of jets. This causes dipole and higher multipole components in the radiated acoustic field. If desired, such radiation components can be avoided or diminished by placing a spherically or dome shaped fine mesh screen over the orifice **65**. Instead of holding pressurized gas, the source **63** may hold a vacuum. In either case, the pulsing of the gaseous flux causes radiation of monopole-type acoustic waves. The source **63** may be replenished by a pump.

Push-pull operation can be achieved in the manner shown in FIG. **3**. An air pump **20**, labelled "PUMP", with flow ports **64**, pressurizes the pressure vessel **21** while drawing a vacuum in the vacuum vessel **22**. A valve **23** is operated by the solenoid **24** such as to alternately admit high and low pressure air to the conduit **26**. The latter vents to the atmosphere through a screen **55** placed across an orifice **27** that is open to the atmosphere. The valve is controlled by an oscillator consisting of the solenoid **24**, which is connected to the pulse generator **6**, labelled "GENERATOR". The frequency of the electric current pulses through the solenoid is determined by the setting of the tuning control **9**. This frequency is to be tuned to the resonance frequency of the sensory resonance that is to be excited. The tuning may be done manually by a user. The conduit **26** is structured as a diffuser in order to avoid boundary layer separation during the exhaust phase; the screen across the orifice **27** inhibits formation of a jet, thereby providing more nearly for a monopole type acoustic wave. During the intake phase the orifice acts as a sink; streamlines **28** of the resulting flow are illustrated. The vessels **21** and **22** smooth the flow fluctuations through the orifice that are due to the flow fluctuations through the pump; they are drawn at a relatively small scale for compactness sake. Instead of the oscillating valve **23**, a rotating valve may be used, driven by a stepper motor powered by voltage pulses from a generator.

Conventional loudspeakers may be used as well as the source of acoustic radiation. An example is shown in FIG. **4**, where the piezoelectric transducer **37** is driven by a simple battery-powered pulse generator built around two RC timers **30** and **31**. Timer **30** (Intersil ICM7555, for instance) is hooked up for astable operation; it produces a square wave voltage with a frequency determined by capacitor **33** and the potentiometer **32**, which serves as a tuner that may be operated by a user. The square wave voltage at output **34** drives the LED **35**, and appears at one of the output terminals **36**, after voltage division by potentiometer **71**. The other output is connected to the negative supply. The output terminals **36** are connected to the piezoelectric speaker. Automatic shutoff of the voltage that powers the timer **30** at point **38** is provided by a second timer **31**, hooked up for monostable operation. Shutoff occurs after a time interval determined by resistor **39** and capacitor **40**. Timer **31** is powered by a 9 Volt battery **41**, via a switch **42**. Optional rounding of the square wave is done by an RC circuit consisting of a resistor **43** and capacitor **44**. An optional airtight enclosure **29** may be used for the speaker **37**, in order to enhance the monopole component of the radiated acoustic signal. Instead of a piezoelectric speaker one may use an electromagnetic loudspeaker with a voice coil. Because of the low impedance of the voice coil, a resistor must then be included in the output circuitry in order to keep the output currents to low values such as to allow battery powering of the device. Small voice coil currents are sufficient for the low acoustic powers required.

Low pulse frequencies can be monitored with the LED **35** of FIG. **3**. The LED blinks on and off with the square wave, and it doubles as a power indicator. The pulse frequency can be determined by reading a clock and counting the LED light pulses. For higher frequencies a monitoring LED can still be used, if it is driven by a signal obtained by frequency division of the generator signal.

The automatic shutoff described above is an example for automatic control of the generated voltage; more sophisticated forms of control involve automatic frequency sequences. A computer that runs a simple timing program can be used for the generation of all sorts of square waves that can be made available at a computer port. An economic and compact version of such arrangement is provided by the Basic Stamp manufactured by Parallax Inc, Rocklin, Calif., which has an onboard EEPROM that can be programmed for the automatic control of the generated pulses, such as to provide desired on/off times, frequency schedules, or chaotic waves. The square waves can be rounded by RC circuits, and further smoothed by integration and filtering.

A compact packaging of the device such as shown of FIG. **4** is depicted in FIG. **5** where all circuit parts and the speaker, piezoelectric or voice-coil type, are contained in a small casing **62**. Shown are the speaker **37**, labelled "SPEAKER", driven by the generator **6**, labeled "GENERATOR", with tuning control **9**, LED **35**, battery **41**, and power switch **42**. The LED doubles as a mark for the tuning control dial. With the circuit of FIG. **4**, the device draws so little current that it can be used for several months as a sleeping aid, with a single 9 Volt battery.

For the purpose of thwarting habituation to the stimulation, irregular features may be introduced in the pulse train, such as small short-term variations of frequency of a chaotic or stochastic nature. Such chaotic or stochastic acoustic pulses can cause excitation of a sensory resonance, provided that the average pulse frequency is close to the appropriate sensory resonance frequency. A chaotic square wave can be generated simply by cross coupling of two timers. FIG. **6** shows such a hookup, where timers **72** and **73**, each labeled "TIMER", have their output pins **74** and **75** connected crosswise to each other's control voltage pins **76** and **77**, via resistors **78** and **79**. The control voltage pins **76** and **75** have capacitors **80** and **81** to ground. If the timers are hooked up for astable operation with slightly different frequencies, and appropriate values are chosen for the coupling resistors and capacitors, the output of either timer is a chaotic square wave with an oval attractor. Example circuit parameters are: R_{78}=440KΩ, R_{79}=700KΩ, C_{80}=4.7 μF, C_{81}=4.7 μF, with $(RC)_{72}$=0.83 s and $(RC)_{73}$=1.1 s. For these parameters, the output **74** of timer **72** is a chaotic square wave with a power spectrum that has large peaks at 0.46 Hz and 0.59 Hz. The resulting chaotic wave is suitable for the excitation of the ½ Hz resonance.

A complex wave may be used for the joint excitation of two different sensory resonances. A simple generator of a complex wave, suitable for the joint excitation of the ½ Hz autonomic resonance and the 2.5 Hz cortical resonance, is shown in FIG. **7**. Timers **82** and **83** are arranged to produce square waves of frequencies f_1 and f_2 respectively, where f_1 is near 2.5 Hz, and f_2 is near ½ Hz. The outputs **84** and **85** of the timers are connected to the inputs of an AND gate **86**. The output **87** of the AND gate features a square wave of frequency f_1, amplitude modulated by a square wave of frequency f_2, as indicated by the pulse train **88**.

The very low frequency waves needed for the acoustic stimulation of the vestibular nerve may also be provided by a sound system in which weak subaudio pulses are added to audible audio program material. This may be done in the customary manner way of adding the currents from these signals at the inverting input of an operational amplifier. The amplitude of the pulses is chosen such that the strength of the resulting acoustic pulses lies in the effective intensity window. Experiments in our laboratory have shown that the presence of audible signals, such as music or speech, does not interfere with the excitation of sensory resonances.

The invention can also be implemented as a sound tape or CD ROM which contains audible audio program material together with subliminal subaudio signals. The recording can be done by mixing the audio and subaudio signals in the usual manner. In choosing the subaudio signal level, one must compensate for the poor frequency response of the recorder and the electronics, at the ultra low subaudio frequencies used.

The pathological oscillatory neural activity involved in epileptic seizures and Parkinson's disease is influenced by the chemical milieu of the neural circuitry involved. Since the excitation of a sensory resonance may cause a shift in chemical milieu, the pathological oscillatory activity may be influenced by the resonance. Therefore, the acoustic excitation discussed may be useful for control and perhaps treatment of tremors and seizures. Frequent use of such control may afford a treatment of the disorders by virtue of facilitation and classical conditioning.

In this as well as in the detuning method discussed before, an epileptic patient can switch on the acoustic stimulation upon sensing a seizure precursor.

Since the autonomic nervous system is influenced by the ½ sensory resonance, the acoustic excitation of the resonance may be used for the control and perhaps the treatment of anxiety disorders.

The invention can be embodied as a nonlethal weapon that remotely induces disorientation and other discomfort in targeted subjects. Large acoustic power can be obtained easily with acoustic monopoles of the type depicted in FIG. **3** or FIG. **12**. If considerable distance needs to be maintained to the subject, as in a law enforcement standoff situation illustrated in FIG. **8**, several monopoles can be used, and it then may become important to have phase differences between the acoustic signals of the individual monopoles arranged in such a manner as to maximize the amplitude of the resultant acoustic signal at the location **52** of the subject. Shown are four squad cars **53**, each equiped with an acoustic monopole capable of generating atmospheric pulses of a frequency appropriate for the excitation of sensory resonances. The relative phases of the emitted pulses are arranged such as to compensate for differences of acoustic path lengths **54**, such that the pulses arrive at the subject location **52** with substantially the same phase, resulting in constructive interference of the local acoustic waves. Such arrangement can be achieved easily by using radio signals between the monopole units, with the target distances either dialed in manually or measured automatically with a range finder. The subaudio acoustic signals can easily penetrate into a house through an open window, a chimney, or a crack under a closed door.

Some of our experiments on acoustic excitation of sensory resonances which provide a basis for the present invention will be discussed presently. Of all the responses to the excitation of the ½ Hz resonance, ptosis of the eyelids stands out for distinctness, ease of detection, and sensitivity. When voluntary control of the eyelids is relinquished, the eyelid position is determined by the relative activities of the sympathetic and parasympathetic nervous systems. There are two ways in which ptosis can be used as an indicator that the autonomic system is being affected. In the first, the subject simply relaxes the control over the eyelids, and makes no effort to correct for any drooping. The more sensitive second method requires the subject to first close the eyes about half way. While holding this eyelid position, the eye are rolled upward, while giving up voluntary control of the eyelids. With the eyeballs turned up, ptosis will decrease the amount of light admitted to the eyes, and with full ptosis the light is completely cut off. The second method is very sensitive because the pressure excerted on the eyeballs by partially closed eyelids increases parasympathetic activity. As a result, the eyelid position becomes somewhat labile, exhibiting a slight flutter. The labile state is sensitive to small shifts in the activities of the sympathetic and parasympathetic systems. The method works best when the subject is lying flat on the back and is facing a moderately lit blank wall of light color.

The frequency at which ptosis is at a maximum is called the ptosis frequency. This frequency depends somewhat on the state of the nervous and endocrine systems, and it initially undergoes a downward drift, rapid at first and slowing over time. The ptosis frequency can be followed in its downward drift by manual frequency tracking aimed at keeping ptosis at a maximum. At a fixed frequency, the early ptosis can be maintained in approximately steady state by turning the acoustic stimulation off as soon as the ptosis starts to decrease, after which the ptosis goes through an increase followed by a decline. The acoustic stimulation is turned back on as soon as the decline is perceived, and the cycle is repeated.

At fixed frequencies near ½ Hz, the ptosis cycles slowly up and down with a period ranging upward from about 3 minutes, depending on the precise acoustic frequency used. The temporal behavior of the ptosis frequency is found to depend on the acoustic pulse intensity; the drift and cycle amplitude are smaller near the low end of the effective intensity window. This suggests that the drift and the cycling of the ptosis frequency is due to chemical modulation, wherein the chemical milieu of the neural circuits involved affects the resonance frequency of these circuits, while the milieu itself is influenced by the resonance in delayed fashion. Pertinent concentrations are affected by production, diffusion, and reuptake of the substances involved. Because of the rather long characteristic time of the ptosis frequency shift, as shown for instance by the cycle period lasting **3** minutes or longer, it is suspected that diffusion plays a rate-controlling role in the process.

The resonance frequencies for the different components of the ½ Hz sensory resonance have been measured, using acoustic sine waves with a sound pressure of 2×10^{-9} N/m^2 at the subject's left ear. Ptosis reached a steady state at a frequency of 0.545 Hz. Sexual excitement occurred at two frequencies, 0.530 Hz and 0.597 Hz, respectively below and above the steady-state ptosis frequency. For frequencies of 0.480 Hz and 0.527 Hz the subject fell asleep, whereas tenseness was experienced in the range from 0.600 to 0.617 Hz.

The resonance near 2.5 Hz may be detected as a pronounced increase in the time needed to silently count backward from 100 to 70, with the eyes closed. The counting is done with the "silent voice" which involves motor activation of the larynx appropriate to the numbers to be uttered, but without passage of air or movement of mouth muscles. The motor activation causes a feedback in the form of a visceral stress sensation in the larynx. Counting with the silent voice is different from merely thinking of the numbers, which does not produce a stress sensation, and is not a sensitive detector of the resonant state. The larynx stress feedback constitutes a visceral input into the brain and may thus influence the amplitude of the resonance. This unwanted influence is kept to a minimum by using the count sparingly in experiment runs. Since counting is a cortical process, the 2.5 Hz resonance is called a cortical sensory resonance, in distinction with the autonomic resonance that occurs near ½ Hz. In addition to affecting the silent counting, the 2.5 Hz resonance is expected to influence other cortical processes as well. It has also been found to have a sleep inducing effect. Very long exposures cause dizziness and disorientation. The frequency of 2.5 Hz raises concerns about kindling of epileptic seizures; therefore, the general public should not use the 2.5 Hz resonance unless this concern has been laid to rest through further experiments.

The sensitivity and numerical nature of the silent count makes it a very suitable detector of the 2.5 Hz sensory resonance. It therefore has been used for experiments of frequency response and effective intensity window. In these experiments, rounded square wave acoustic pulses were produced with a frequency that was slowly diminished by computer, and the subject's 100–70 counting time was recorded for certain frequencies. The acoustic transducer was a small loudspeaker mounted in a sealed cabinet such as to provide acoustic monopole radiation. At fixed frequency, the acoustic monopole strenght in m^3/s varies linearly with the voice coil current, with a constant of proportionality that can be calculated from measured speaker dome excursions for given currents. The sound pressure level at the entrance of the subject's nearest external ear canal can be expressed in terms of the acoustic monopole strength and the distance from the loudspeaker. For each experiment run, the sound pressure level at the entrance of the subject's external ear canal can thus be calculated from the measured amplitude of the voice coil current and the pulse frequency. Since for the subaudio frequencies the distance from the acoustic radiator to the subject's ear is much smaller than the wavelength of the sound, the near-field approximation was used in this calculation. The sound pressure level was expressed in dB relative to the reference sound pressure of 2×10^{-5} N/m^2. This reference pressure is traditionally used in the context of human hearing, and it represents about the normal minimum human hearing threshold at 1.8 KHz.

FIG. **9** shows the result of experiment runs at sound pressure levels of −67, −61, −55, and −49 dB. Plotted are the subject's 100–70 counting time versus pulse frequency in a narrow range near 2.5 Hz. Resonance is evident from the sharp peak **57** in the graph for the sound pressure level of −61 dB. The graphs also reveal the effective intensity window for the stimulation, as can be seen by comparing the magnitude of the peaks for the different sound pressure levels. For increasing intensity, the magnitude of the peak first increases but then decreases, and no significant peak shows up in the graph for the largest sound pressure of −49 dB; this can be seen better from the insert **58**, which shows the graphs for −67 and −49 dB in a magnified scale. It follows that the effective intensity window extends approximately from −73 to −49 dB, in terms of the sound pressure level at the entrance of the subject's external ear canal.

The physiological response to the 2.5 Hz acoustic stimulation can be avoided by wearing earplugs. FIG. **10** is a plot of the 100–70 counting time versus acoustic pulse frequency, with and without earplugs. The sound pressure level at the entrance of the subject's external ear canal was −6 dB for both runs. Without earplugs the counting time has the peak **59**, but no significant peak is seen in graph **60** for the run in which the subject used earplugs. Two conclusions can be reached from these results. First, in the experiments the 2.5 Hz resonance is essentially excited acoustically rather than through the magnetic field induced by the voice coil currents in the loudspeaker. Second, it follows that the exciting sound essentially propagates via the external ear canal, instead of through the skin and bones in the area of the ears, or via cutaneous mechanoreceptors in the skin at large.

To answer the question whether the acoustic excitation of the 2.5 Hz sensory resonance occurs perhaps through the cochlear nerve, one needs to consider the human auditory threshold curve such as shown, for instance, by Thomson (1967). The curve has a minimum near 1.8 KHz where the threshold sound pressure level is 0 dB, by definition. At 10 Hz the threshold is 105 dB. Hence, the pronounced acoustic excitation of the sensory resonance shown in FIG. **9** for a sound pressure level of −61 dB is 166 dB below the auditory threshold at 10 Hz. The excitation occurs near 2.5 Hz, and at that frequency, the auditory threshold is even higher than at 10 Hz. Although the curve in Thomson's book does not go below 10 Hz, linear extrapolation suggests the estimate of 135 dB for the threshold at 2.5 Hz, bringing the sound pressure level that is effective for acoustic excitation of the sensory resonance to 196 dB below the estimated threshold at the frequency near 2.5 Hz used. This result all but rules out excitation via the cochlear nerve.

Chemical modulation may be the cause for the small frequency difference for peaks **57** and **59** in FIGS. **9** and **10**, for the sound pressure level of −61 dB; these peaks occur respectively at 2.516 and 2.553 Hz.

The physiological response to the excitation of the sensory resonances at a fixed stimulus frequency is not immediate but builds over time. An example is shown in FIG. **11**, where the graph **61** depicts the measured 100–70 time plotted versus elapsed time, upon application of acoustic pulses of 2.558 Hz frequency and a sound pressure level of −61 dB. The graph shows that the response is initially delayed over about 5 minutes; thereafter it increases, and at about 22 minutes the slope is seen to decrease somewhat. Other experiments have shown a counting time that eventually settles on a plateau, or even starts on a decline. Chemical modulation and habituation could account for these features. The response curve depends strongly on initial conditions.

The method is expected to be effective also on certain animals, and applications to animal control are therefore envisioned. The nervous system of mammals is similar to that of humans, so that the sensory resonances are expected to exist, albeit with different frequencies. Accordingly, in the present invention subjects are mammals.

The described method and apparatus can be used beneficially by the general public and in clinical work. Unfortunately however, there is the possibility of mischievous use as well. For instance, with small modifications the method of FIG. **1** can be employed to imperceptibly modulate the air flow in air conditioning or heating systems that serve a home, office building, or embassy, for covert manipulation of the nervous systems of occupants.

The invention is not limited by the embodiments shown in the drawings and described in the specification, which are given by way of example and not of limitation, but only in accordance with the scope of the appended claims.

I claim:

1. Apparatus for manipulating the nervous system of a subject, the subject having an ear, comprising:

generator means for generating voltage pulses;

induction means, connected to the generator means and responsive to the voltage pulses, for inducing at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz.

2. The apparatus according to claim **1**, further comprising means for automatically controlling the voltage pulses.

3. The apparatus according to claim **1**, further comprising means for monitoring the voltage pulses.

4. The apparatus according to claim **1**, for exciting in the subject a sensory resonance that occurs at a resonance frequency less than 15 Hz, the apparatus further comprising tuning means for enabling a user to tune the pulse frequency to the resonance frequency.

5. The apparatus according to claim **4**, further including a casing for containing the generator means, the induction means and the tuning means.

6. The apparatus according to claim **1**, wherein said induction means comprise:

means for generating in the atmosphere a gas jet, the latter having a momentum flux; and

modulation means, connected to the generator means and responsive to said voltage pulses, for pulsing the momentum flux with a frequency less than 15 Hz;

whereby subaudio acoustic pulses are induced in the atmosphere.

7. Apparatus for manipulating the nervous system of a subject, the subject having an ear, comprising:

generator means for generating voltage pulses;

a source of gas at a pressure different from the ambient atmospheric pressure;

a conduit having an orifice open to the atmosphere for passing a gaseous flux;

valve means, connected to the source of gas and the conduit to control the gaseous flux;

means, connected to the generator means and responsive to said voltage pulses, for operating the valve means to provide an oscillation of the gaseous flux with a frequency less than 15 Hz.

8. The apparatus according to claim **7**, further comprising vessel means for smoothing fluctuations of the gaseous flux caused by fluctuations in the pressure of the source of gas.

9. A method for manipulating the nervous system of a subject, the subject having an ear, comprising the steps of:

generating voltage pulses; and

inducing, in a manner responsive to the voltage pulses, at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz.

10. The method according to claim **9**, for exciting in the subject a sensory resonance that occurs at a resonance frequency less than 15 Hz, further comprising the step of tuning the pulse frequency to the resonance frequency.

11. The method according to claim **9**, wherein said inducing comprises the steps of:

generating in the atmosphere a gas jet, the latter having a momentum flux; and

modulating the momentum flux in pulse-wise fashion in a manner responsive to the voltage pulses.

12. The method according to claim **11**, further comprising the step of directing the gas jet at a material surface.

13. The method according to claim **9**, wherein said inducing comprises the steps of:

generating a gas flow through a conduit orifice that is open to the atmosphere; and

modulating the gas flow to produce flow pulsations, in a manner responsive to the voltage pulses.

14. A method for remotely manipulating the nervous system of a subject in the course of law enforcement in a standoff situation, the subject having an ear, comprising the steps of:

generating voltage pulses;

generating, in a manner responsive to the voltage pulses, atmospheric acoustic signals at a plurality of locations remote from the subject for inducing at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz, the signals having phase differences with respect to each other arranged to cause constructive acoustic wave interference at the subject.

15. A method for exciting in a subject a sensory resonance having a resonance frequency less than 15 Hz, the subject having an ear, comprising the steps of:

generating voltage pulses;

inducing, in a manner responsive to the voltage pulses, at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz;

tuning the pulse frequency to the resonance frequency; and also

inducing audible audio-frequency atmospheric acoustic signals at the ear.

16. A method for controlling in a subject neurological disorders that involve pathological oscillatory activity of neural circuits, the subject having an ear, comprising the steps of:

generating voltage pulses;

inducing, in a manner responsive to the voltage pulses, at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz; and

arranging said pulse frequency to detune the pathological oscillatory activity.

17. A method for controlling in a subject epileptic seizures, the subject having an ear, comprising the steps of:

generating voltage pulses;

inducing in a manner responsive to the voltage pulses, at the ear subliminal atmospheric acoustic pulses with a pulse frequency less than 15 Hz; and

initiating said inducing when a seizure precursor is felt by the subject.

[57] **ABSTRACT**

This invention relates to the field of electrical technology, and relates particularly to a method for the continuous transformation of electrical energy with its subsequent transmission from an initial source (transformer) to a consuming device, and also to an apparatus for the implementation of this method of transformation and the supplying of power to electrical devices through a transmission line which does not form a closed circuit, ie consists of a single conducting wire. This invention therefore provides a method and associated apparatus for supplying power to an electrical device(s), including generation and subsequent transmission thereof to a receiving device via a transmission line, the method being characterised by the transformation of the electrical energy which is generated into the energy of oscillation of a field of free electrical charges such as the displacement current or longitudinal wave of an electrical field, the density of which charges varies in time, and the transmission of the energy via a transmission line which does not form a closed circuit comprising a single-wire transmission line and, where necessary, its transformation into the electromagnetic energy of conduction currents.

METHOD AND APPARATUS FOR SINGLE LINE ELECTRICAL TRANSMISSION

FIELD OF TECHNOLOGY

This invention relates to the field of electrical technology, and relates particularly to a method for the continuous transformation of electrical energy with fits subsequent transmission from an initial source (transformer) to a consuming device, and also to an apparatus for the implementation of this method of transformation and the supplying of power to electrical devices through a transmission line which does not form a closed circuit, ie consists of a single conducting wire.

BACKGROUND ART

There exists a means for the transmission of electrical energy along a conducting wire which does not form a closed circuit ie, a single conducting wire. It is based on the discovery in 1729 by the English physicist Stephen Grey of the phenomenon of electrical conductivity. The essence of this phenomenon consists in the fact that electricity may be transmitted from one body to another along a metal conductor or a length of yarn, and that the electrical charge is distributed over the surface of the conductor.

See Yu. A. Khramov, *Physicists: A Biographical Reference Book* (Moscow, "Nauka" 1983) (in Russian); and *Dictionary of scientific biography* (New York, Charles Scribener's Sons 1970–1978).

As to closed circuits, a well known means for the supplying of power to electrical devices has existed since the creation in 1799 by the Italian scientist Alessandro Volta of the first source of prolonged electrical current (Volta's column). This means is based on the transmission of electrical energy generated in the initial source to the consuming device directly through a transmission line consisting of two conducting wires which together with the source and the load form a closed circuit.

See Yu. A. Khramov, *Physicists: A Biographical Reference Book,* M. I. Radovsky, *Galvani and Volta* (Moscow-Leningrad 1941) (in Russian); and G. Polvani, *Alessandro Volta* (Pisa 1942).

There exists another important type of closed circuit that represents a means for the supply of power to electrical devices based on the discovery made by M Faraday and J Henry of the phenomenon of electromagnetic induction (published by M Faraday in 1831, and on the invention by P N Yablochkov in 1876 of the electrical transformer. The essence of this means consists in the transformation of the current or the voltage of electrical energy generated in the initial source and the transmission line to the consuming device.

See M. Faraday, *Experimental Research in Electricity* (Moscow-Leningrad, Publishing House of the Academy of Sciences of the USSR 1947–1959) (in Russian); Yu. A. Khramov, *Physicists: A Biographical Reference Book; The Large Soviet Encyclopedia,* 3rd Ed. (Bol 26 Moscow, "Soviet Encyclopedia" 1977) (in Russian).

As to wireless means, there exists a means for the supplying of power to electrical and radio devices by using an electromagnetic field. This means is based an G Herz's experimental proof in 1888 of the existence of electromagnetic waves, the discovery of which was forecast by J Maxwell in 1865. The means essentially consists in the transformation of electrical energy from the initial source into an electromagnetic field which is radiated into space and received by the consuming device.

Dictionary of Scientific Biography. New York, Charles Scribener's Sons, 1970–1978. Yu A Khramov, Physicists: A Biographical Reference Book. Moscow, "Nauka", 1983 (in Russian); J K Maxwell, Selected Works on Electromagnetic Field Theory, Moscow "Gosizdat", 1954 (in Russian).

There also exists an electrical device for the transmission of the energy of free electrical charges from the initial source by means of a non-conducting ribbon. This is the so-called high voltage electrostatic generator, which was designed and constructed by the American physicist Van de Graaf between 1929 and 1933. In this device electrical charges are sprayed from needles under high voltage on to a moving ribbon and transferred to an insulated metal dome, where they accumulate. The charges may be sprayed on to the ribbon and collected from it; the ribbon and the dome may be negatively or positively charged.

See K. E. Swarts, *The Uncommon Physics of Common Phenomena,* Vol. 2, translated from the English by E. I. Butikov and A. S. Kondratiev (Moscow 1987) (in Russian); *Biography;* and Yu. A. Khramov, *Physicists: A Biographical Reference Book.*

It is believed to have been proposed to provide a means for the supply of power to electrical devices via a single-wire transmission line, demonstrated by N Tesla in the late nineteenth century.

See John O'Neill, *Electrical Prometheus,* (Moscow "History of Technology" 1944) (in Russian); B. N. Rzhonsnitsky, *Nikola Tesla* (Moscow "Molodaya Gvardiya" 1959) (in Russian); and G. K. Tsverava, *Nikola Tesla* (Leningrad "Nauka" 1974) (in Russian).

It is believed there is a trace mentioned by John O'Neill of one more distinctive means for electrical transmission but description of this trade did not have details and was not confirmed by any original document.

OBJECTS OF THE INVENTION

An object of the present invention is to provide an increase of the coefficient of efficiency to transmission from an initial source to a consuming device in electrical technology, and also a simultaneous reduction in the metal content of the transmission line.

SUMMARY OF THE INVENTION

According to a first aspect of the present invention there is provided a method of supplying power to one or more electrical devices, including generation and transformation of electrical energy and subsequent transmission thereof to a receiving device via a transmission line, the method being chracterised by the transformation of the electrical energy which is generated into the energy of oscillation of a field of free electrical charges such as a displacement current or longitudinal wave of an electrical field, the density of which charges varies in time, and the transmission of the energy via a transmission line which does not form a closed circuit comprising a single-wire transmission line and, where necessary, its transformation into the electromagnetic energy of conduction currents.

Thus, the invention provides transformation of electrical energy generated in an initial source into energy of oscillation of a field of free electrical charges (the displacement current or longitudinal wave of the electrical field), which energy is transmitted to the consuming device via a conductor of the transmission line which does not form a closed circuit and, where necessary, transformed into the electromagnetic energy of closed circuit conductive currents.

The oscillations of the field of free electrical particles occur either by means of the reciprocating (cyclical) displacement of a concentrated electrical charge in space, or by means of a periodical change in density (and/or polarity) of the free electrical charges on a particular surface (in a particular volume).

According to a second aspect of the present invention there is provided an apparatus for the implementation of the above method of supplying power to one or more electrical devices, the apparatus providing an initial source of electrical energy, a transforming device, a transmission line and a receiving device, the apparatus being characterised by the provision of a variable density generator of free electrical charges as the displacement current or longitudinal wave of an electrical field, an output of which is connected by means of: a conductor of a transmission line which does not form a closed circuit to a receiving device, either directly or via a blocking capacitor, and further to any conductive body possessing an equivalent (natural) capacity adequate to ensure the normal functioning of the receiving device.

Thus, the invention provides a variable (alternating) density generator of free electrical charges, which flow under the influence of coulomb forces along a conductor of the transmission line which does not form a closed circuit to the site of a device which consumes electrical energy.

A possible variant of the generator is a generator at the outlet of which not only the density of the free electrical charges, but also their polarity, may be varied.

The outlet of the generator is connected to a conductor of the transmission line which does not form a closed circuit line either directly or via a blocking capacitor.

In addition, the generator of oscillations of the electrical field of free charges may be constructed in a similar fashion to a generator of displacement current (travelling longitudinal waves of an electrical field), by using a sequential resonance circuit in the form of two interconnected inductors such that the equivalent inductivity of the resonance circuit is provided by their resultant inductivity, and the equivalent capacity of the resonance circuit is provided by the equivalent (natural) capacity of the interconnected inductors.

To supply power to electrical devices which consume alternating current, the output of the conductor of the transmission line which does not form a closed circuit may be connected:

a) to one of the input terminals of the receiving devices, while the device's other input terminal is either grounded or connected to any conductor possessing a natural (equivalent) capacity adequate to provide for the normal working of the receiving (consuming) device.

b) to an accommodating device employing a conversion circuit consisting of two interconnected inductors, such that the receiving device (load) is connected to the two ends of the first inductor, the output of the conductor of the transmission line which does not form a closed circuit is connected to one end of the second inductor, and the other end of the second inductor connected to any conductor with an equivalent (natural) capacity and inductance selected in order to provide for the nominal power consumption of the receiving device (load).

To supply power to devices consuming direct current, the conductor of the transmission line which does not form a closed circuit may be connected to an adjustment circuit in the form of:

c) a diode system, such that the output of the conductor of the transmission line which does not fort a closed circuit is connected to the common point of the anode of the first diode and the cathode of the second diode, while the cathode of the first diode and the anode of the second diode are the output points for connection to the receiving device, either directly or with a capacitor connected in parallel.

d) a transformer circuit consisting of two interconnected inductors such as to rectify alternating current (voltage) directed to the receiving device from the first inductor.

BRIEF DESCRIPTION OF THE DRAWINGS

In order to provide a better understanding of the invention, there follow specific examples of its construction with references to the drawings attached, in which:

FIG. **1** shows a block diagram of a first embodiment of an apparatus according to the present invention;

FIG. **2** shows a schematic diagram of a second embodiment of an apparatus according to the present invention, employing a sequential resonance circuit;

FIG. **3** shows a power supply diagram for receiving devices operating on alternating current;

FIG. **4** shows a power supply diagram for receiving devices operating on direct current.

DESCRIPTION OF FIRST EMBODIMENT

The first embodiment of the invention provides apparatus adapted for use in a method of supplying power to electrical devices, including the generation and transformation of electrical energy with its subsequent transmission to a receiving device via a transmission line, the method being distinguished by the fact that the electrical energy generated is transformed into the energy of oscillation of a field of free electrical charges (the displacement current or longitudinal wave of an electrical field), the density of which charges varies in time, and this energy is transmitted via a conductor of the transmission line which does not form a closed circuit and, where necessary, transformed into the electromagnetic energy of conductive currents.

Referring to FIG. **1**, there is illustrated an apparatus for initial source of electrical energy **1**, a transformer (of current, voltage or frequency) **2**, an alternating density generator of free electrical charges **3**, which charges flow under the influence of coulomb forces along a transmission line or conductor **4**, through a consuming device **5**, to any conductive body **6**, which has an equivalent (natural) capacity sufficient to provide for the normal working of the consuming device **5**.

DESCRIPTION OF SECOND EMBODIMENT

Referring to FIG. **2**, in addition, the apparatus may be constructed on the basis of a generator of displacement current (longitudinal wave of an electrical field), using a sequential resonance circuit (FIG. **2**) in the form of two interconnected inductors L**1** and L**2** such that an equivalent inductivity Leg of the resonance circuit is provided, in the simplest case of idle running, by the resultant inductivity L**1** and L**2**, and the equivalent capacity is provided by the resultant (natural) capacity of the resonance circuit.

To supply power to electrical devices operating on alternating (variable) current, the output of the conductor of the transmission line which does not form a closed circuit **4** is connected either:

to one of the input terminals Bx**1** of the receiving device **5** (FIG. **3**), and the other input terminal Bx**3** of the receiving device is either earthed or connected to any conductive body **6** possessing an equivalent (natural) capacity adequate to ensure the normal working of the receiving device **5**; or

to an accommodating device, employing a transformer circuit (FIG. **3**) consisting of two interconnected inductors L**3** and L**4**, such that the two ends Bx**3** and Bx**4** of the inductor L**3** are connected to the receiving device **5**, while one end of the ends Bx**5** of the second inductor L**4** is connected to the output of the conductor of the transmission line which does not form a closed circuit **4**, and the other end Bx**6** of the inductor L**4** is connected to any conductive body **6**, with an equivalent (natural) capacity selected in order to provide the nominal power consumption of the receiving device **5**.

To supply power to electrical devices operating on direct current, the output of the conductor of the transmission line which does not form a closed circuit **4** is connected to an accommodation circuit in the form of either:

a diode circuit (FIG. **4**) such that output or the conductor **4** is connected to the common point of the anode of the first diode VD**1** and the cathode of the second diode VD**2**, while the cathode of the first diode VD**1** and the anode of the second diode VD**2** are the outlets **01** and **02** to be connected to the receiving device **5**, either directly or with a capacitor connected in parallel;

a transformer circuit (FIG. **4**) employing two interconnected inductors L**5**, L**6**, such that the receiving device **5** is connected to the inductor L**5** via the rectifying circuit.

The method for supply of power to electrical devices and the apparatus for the implementation of this method, according to the invention, possess a high degree of reliability due to the absence of complex electronic or mechanical assemblies. They permit the use of inexpensive mass-produced radio-electronic components and their working cycle is automatically regulated to a high degree.

Use of the invention will make possible a sharp reduction in the costs involved in transmitting electrical energy over long distances, and a sharp reduction in the losses of Joulean heat from transmission lines.

The invention is intended for the creation of a highly efficient means for the transformation and transmission of electrical energy, and also for the creation of both permanent and mobile devices for the transmission of electrical energy from an initial source to a consuming device via a transmission line which does not form a closed circuit, ie a single-wire transmission line.

The invention may be used conjointly with various power-engineering and technological processes which involve the use of super-high voltage electrical and electromagnetic fields, electron beams and super-long wave radio communications, when it will make possible a sharp reduction in the dimensions and weight of equipment as compared with the means traditionally employed.

The proposed apparatus, which may be termed a "monovibrator", may consist of two inductively connected much layered coils in accordance with the scheme of a consecutive resonance circuit. As a rule, the secondary coil consists of up to some tens of thousands of turns of thin isolated wire with the turns wound one to another in many layers on a dialectic core. Disposition of the primary coil in respect to the secondary one doesn't matter much. What does matter is an inductive link which determines potential transmitted from the primary to the secondary coil. The monovibrator may or may not have a ferromagnetic core. The ferromagnetic core influences the width of the working frequency bandwidth—it broadens it.

High working outcoming voltage is the result of a high coefficient of transformation, as the primary coil usually contains a couple of dozens of winds for working frequencies ranging from 1 kHz to a couple of hundred kHz. A preferred working frequency is 5 kHz.

With a sequential resonance circuit including two interconnected inductors having inductance L**1** and L**2**, and an equivalent inductance of the resonance circuit being provided by the resultant inductivity L**1**+L**2**, the load of the monovibrator when running idle acquires capacitance character that means which it is reactive. The magnitude of an active constituent of a monoconductive line with the consecutive resonance is rather low and its incoming resistance is approaching zero. That is why with rather a powerful primary source the consecutive resonance makes it possible to transmit more power through the monoconductive line in case there is an outtake of this power at the other line terminal, which is opposite to the primary source of power.

Reaction of the monoconductive line of any length can always be compensated by regulating the frequency of the primary source (generator, converting devices), thus providing consecutive resonance in the line itself with all the magnitudes of incoming and outgoing characteristics arising therefrom.

Currently there are different schemes of automatic frequency regulation of generators of alternating electromotive power depending on changing inductive-capacitant parameters of conductive lines.

The method and apparatus of the present invention does not have the drawbacks of previously known single line systems.

What is claimed is:

1. A method of supplying power to at least one receiving electrical device, comprising the steps of:

(a) generating electrical energy;

(b) transforming the electrical energy generated in said step (a) into the oscillation energy of a field of free electrical charges, the density of which varies in time;

(c) transmitting the electrical energy transformed in said step (b) to a receiving electrical device via a single-wire transmission line.

2. The method of claim **1**, wherein in said step (b), the oscillation energy of a field of free electrical charges comprises a displacement current of an electrical field.

3. The method of claim **2**, further comprising the step of:

(d) following said step (b) and prior to said step (c), transforming the displacement current into a conduction current for use by an electrical device powered by conduction current.

4. Apparatus for supplying power to at least one electrical device, comprising:

an initial source of electrical energy,

a transformer operatively connected to said initial source to receive electrical energy therefrom; an alternating density generator for transforming the electrical energy from said transformer into an aggregate of free electrical charges, the density of which varies in time;

a single-wire transmission line, said transmission line including a conductor connecting the output of said alternating density generator to a receiving device; and

a conductive body electrically connected to the receiving device, said conductive body having a charge storage capacity of a magnitude adequate to ensure normal functioning of the receiving device.

5. The apparatus of claim **4**, further comprising a blocking capacitor interposed between said transmission line and the receiving device.

6. The apparatus of claim **4**, wherein said alternating density generator comprises a sequential resonance circuit including two interconnected inductors having inductance L1 and L2, and an equivalent inductance of said resonance circuit being provided by the resultant inductivity L1+L2.

7. The apparatus of claim **4**, wherein said alternating density generator transforms the electrical energy from said generator into a displacement current.

8. The apparatus of claim **4**, wherein said alternating density generator transforms the electrical energy from said generator into a longitudinal wave of an electrical field.

9. The apparatus of claim **6**, wherein the electrical device operates on alternating current, and wherein said apparatus further comprises an accommodating device connected to said conductor of said transmission line, said accommodating device including a transformer circuit including at least first and second interconnected inductors, each of said inductors having first and second ends, said first and second ends of said first inductor being connected to the receiving device, said first end of said second inductor connecting said accommodating device to the output of said conductor of said transmission line, and said second end of said second inductor being connected to said conductive body.

10. The apparatus of claim **6**, wherein the electrical device operates on direct current, said apparatus further comprising first and second accommodating devices selectively connectable to said conductor of said transmission line, wherein:

said first accommodating device comprises a diode circuit including first and second diodes, said first diode having an anode and said second diode having a cathode which are commonly connected to the output of said conductor of said transmission line, said first diode having a cathode and said second diode having an anode defining outlets connected to the receiving device; and

said second accommodating device comprises a transformer circuit including first and second interconnected inductors and a rectifying circuit connecting one of said first and second inductors to the receiving device.

11. The apparatus of claim **6**, wherein said first and second interconnected inductors comprise first and second inductively connected coils arranged in accordance with the scheme of a consecutive resonance contour, said second coil comprising a plurality of turns of isolated wire wound around a dielectric body.

12. The apparatus of claim **10**, wherein said diode circuit of said first accommodating device further includes a capacitor connected in parallel with said cathode of said first diode and said anode of said second diode.

13. The apparatus of claim **11**, wherein said first and second inductors have a ferromagnetic core.

14. Apparatus for supplying power to at least one electrical device, comprising:

an initial source of electrical energy;

an alternating density generator for transforming the electrical energy from said source into the oscillation energy of a field of free electrical charges, the density of which varies with time;

a single-wire transmission line, said transmission line including a conductor connecting the output of said alternating density generator to a receiving device; and

a conductive body electrically connected to the receiving device, said conductive body having a charge storage capacity of a magnitude adequate to ensure normal functioning of the receiving device.

15. The apparatus of claim **14**, further comprising a blocking capacitor interposed between said transmission line and the receiving device.

16. The apparatus of claim **14**, wherein said alternating density generator comprises a sequential resonance circuit including two interconnected inductors having inductance L1 and L2, and an equivalent inductance of said resonance circuit being provided by the resultant inductivity L1+L2.

17. The apparatus of claim **16**, wherein said alternating density generator transforms the electrical energy from said generator into a displacement current.

18. The apparatus of claim **16**, wherein said alternating density generator transforms the electrical energy from said generator into a longitudinal wave of an electrical field.

19. The apparatus of claim **16**, wherein the electrical device operates on alternating current, and wherein said apparatus further comprises an accommodating device connected to said conductor of said transmission line, said accommodating device including a transformer circuit including at least first and second interconnected inductors, each of said inductors having first and second ends, said first and second ends of said first inductor being connected to the receiving device, said first end of said second inductor connecting said accommodating device to the output of said conductor of said transmission line, and said second end of said second inductor being connected to said conductive body.

20. The apparatus of claim **16**, wherein the electrical device operates on direct current, said apparatus further comprising first and second accommodating devices selectively connectable to said conductor of said transmission line, wherein:

said first accommodating device comprises a diode circuit including first and second diodes, said first diode having an anode and said second diode having a cathode which are commonly connected to the output of said conductor of said transmission line, said first diode having a cathode and said second diode having an anode defining outlets connected to the receiving device; and

said second accommodating device comprises a transformer circuit including first and second interconnected inductors and a rectifying circuit connecting one of said first and second inductors to the receiving device.

21. The apparatus of claim **20**, wherein said diode circuit of said first accommodating device further includes a capacitor connected in parallel with said cathode of said first diode and said anode of said second diode.

22. The apparatus of claim **16**, wherein said first and second interconnected inductors comprise first and second inductively connected coils arranged in accordance with the scheme of a consecutive resonance contour, said second coil comprising a plurality of turns of isolated wire wound around a dielectric body.

23. The apparatus of claim **22**, wherein said first and second inductors have a ferromagnetic core.

(57) **ABSTRACT**

This invention relates to apparatus for the conversion of massfree energy into electrical or kinetic energy, which uses in its preferred form a transmitter and a receiver both incorporating Tesla coils, the distal ends of whose secondary windings are co-resonant and connected to plates of a chamber, preferably evacuated or filled with water, such that energy radiated by the transmitter may be picked up by the receiver, the receiver preferably further including a pulsed plasma reactor driven by the receiver coil and a split phase motor driven by the reactor. Preferably the reactor operates in pulsed abnormal gas discharge mode, and the motor is an inertially damped drag motor. The invention also extends to apparatus in which an otherwise driven plasma reactor operating in pulsed abnormal gas discharge mode in turn used to drive an inertially damped drag motor.

FIG. 19

ENERGY CONVERSION SYSTEMS

This is a continuation of application Ser. No. 09/907,823, filed Jul. 19, 2001 now abandoned.

FIELD OF THE INVENTION

This invention relates to systems for the conversion of energy, inter alia in the form of what we will refer to for convenience as Tesla waves (see below), to conventional electrical energy.

BACKGROUND OF THE INVENTION

Energy converters that are fed by local or environmental energy are usually explained by taking recourse to the notion that they convert zero point electromagnetic radiation (ZPE) to electric energy. The ZPE theories have gained a life of their own, as T. Kuhn has pointed out (in his “Black Body Theory and the Quantum”), after emerging from Planck’s second theory, specifically from the term $\frac{1}{2} h\upsilon$ in the new formula for oscillator energy. In 1913, Einstein and Stern suggested that motional frequencies contributing to specific heat fell into two categories—those that were independent of temperature and those that were not (e.g. rotational energy), leading them to conclude that zero-point energy on the order of $\frac{1}{2} h\upsilon$ was most likely. In the second part of their paper, however, they provided a derivation of Planck’s Law without taking recourse to discontinuity, by assuming that the value of the ZPE was simply $h\upsilon$. It is worth noting that Einstein had already in 1905 (“Erzeugung und Verwandlung des Lichtes betreffenden heuristichen Gesichtspunkt”, Ann. d. Phys, 17, 132) framed the problem of discontinuity, even if only heuristically, as one of placing limits upon the infinite energy of the vacuum state raised by the Rayleigh-Jeans dispersion law. According to Einstein, the Rayleigh-Jeans law would result in an impossibility, the existence of infinite energy in the radiation field, and this was precisely incompatible with Planck’s discovery—which suggested instead that at high frequencies the entropy of waves was replaced by the entropy of particles. Einstein, therefore, could only hope for a stochastic validation of Maxwell’s equations at high frequencies “by supposing that electromagnetic theory yields correct time-average values of field quantities”, and went on to assert that the vibration-energy of high frequency resonators is exclusively discontinuous (integral multiples of $h\upsilon$).

Since then, ZPE theories have gone on a course independent from Planck’s second theory. The more recent root of modern ZPE theories stems from the work of H. Casimir who, in 1948, apparently showed the existence of a force acting between two uncharged parallel plates. Fundamentally the Casimir effect is predicated upon the existence of a background field of energy permeating even the ‘vacuum’, which exerts a radiation pressure, homogeneously and from all directions in space, on every body bathed in it. Given two bodies or particles in proximity, they shield one another from this background radiation spectrum along the axis (i.e. the shortest distance) of their coupling, such that the radiation pressure on the facing surfaces of the two objects would be less than the radiation pressure experienced by all other surfaces and coming from all other directions in space. Under these conditions, the two objects are effectively pushed towards one another as if by an attractive force. As the distance separating the two objects diminishes, the force pushing them together increases until they collapse one onto the other. In this sense, the Casimir effect would be the macroscopic analogy of the microscopic van der Waals forces of attraction responsible for such dipole-dipole interactions as hydrogen bonding. However, it is worth noting that the van der Waals force is said to tend to establish its normal radius, or the optimal distance between dipoles, as the distance where the greatest attractive force is exerted, beyond which the van der Waals forces of nuclear and electronic repulsion overtake the attraction force.

Subsequently, another Dutch physicist, M. Sparnaay, demonstrated that the Casimir force did not arise from thermal radiation and, in 1958, went on to attribute this force to the differential of radiation pressure between the ZPE radiation from the vacuum state surrounding the plates and the ZPE radiation present in the space between them. Sparnaay’s proposal is that a classical, nonquantal, isotropic and ubiquitous electromagnetic zero-point energy exists in the vacuum, and even at a temperature of absolute zero. It is further assumed that since the ZPE radiation is invariant with respect to the Lorentz transformations, it obeys the rule that the intensity of its radiation is proportional to the cube of the frequency, resulting in an infinite energy density for its radiation spectrum.

What appeared to be the virtue of this reformulated theory was the notion that the vacuum no longer figured as pure space empty of energy, but rather as a space exposed to constantly fluctuating ‘fields of electromagnetic energy’.

Puthoff has utilized the isomorphism between van der Waals and Casimir forces to put forth the zero-point (ZP) energy theory of gravity, based on the interpretation that the virtual electromagnetic ZP field spectrum predicted by quantum electrodynamics (QED) is functionally equivalent to an actual vacuum state defined as a background of classical or Maxwellian electromagnetic radiation of random phases, and thus can be treated by stochastic electrodynamics (SED). Whereas in QED, the quanta are taken as virtual entities and the infinite energy of the vacuum has no physical reality, for SED, the ZPE spectrum results from the distortion of a real physical field and does not require particle creation. Gravity then, could be seen as but the macroscopic manifestation of the Casimir force.

We do not dispute the fact that even in space absent matter there is radiant energy present which is not of a thermal nature. But we claim that this energy is not electromagnetic, nor is its energy spectrum infinite. That this is so stems not just from our opinion that it is high time that Einstein’s heuristic hypothesis should be taken as literally factual—in the dual sense that all electromagnetic energy is photon energy and all photons are local productions, but above all from the fact that it is apparent, from the experiments of Wang and his colleagues (Wang, Li, Kuzmich, A & Dogariu, A. “Gain-assisted superluminal light propagation”, Nature 406; #6793; 277), that the photon stimulus can propagate at supraluminal speeds and lies therefore well outside of any scope of electromagnetic theory, be this Maxwell’s classical approach taken up by ZPE theories, or Einstein’s special relativistic phenomenology of Maxwell’s theory. The fact is that if the light stimulus can propagate at speeds greater than those of light, then what propagates is not light at all, and thus not energy configured electromagnetically. Light is solely a local production of photons in response to the propagation of a stimulus that itself is not electromagnetic.

It is critical to understand that the implication from this that—aside from local electromagnetic radiation and from thermal radiation associated with the motions of molecules (thermo-mechanical energy), there is at least another form of energy radiation which is everywhere present, even in space absent matter. Undoubtedly, it is that energy that prevents any attainment of absolute zero, for any possible local outpumping of heat is matched by an immediate local conversion of some of this energy into a minimum thermal radiation required by the manifolds of Space and Time. And undoubtedly also this radiation is ubiquitous and not subject to relativistic transformations (i.e. Lorentz invariant). What it is not, is electromagnetic radiation consisting of randomistic phases of transverse waves.

To understand this properly, one must summarize the differences from existing ZPE theories—and all these differences come down to the fact that this energy which is neither electromagnetic nor thermal per se (and is certainly not merely thermo-mechanical), has nevertheless identifiable characteristics both distributed across subtypes or variants and as well common to all of them.

Essentially the first subtype or variant consists of longitudinal massfree waves that deploy electric energy. They could well be called Tesla waves, since Tesla-type transformers can indeed be shown experimentally to radiate massfree electric energy, in the form of longitudinal magnetic and electric waves having properties not reduceable to photon energy or to 'electromagnetic waves', and having speeds of displacement that can be much greater than the limit c for all strictly electromagnetic interactions.

One may well denote the second subtype by the designation of massfree thermal radiation, since it contributes to temperature changes—and, as obviously indicated by the impossibility of reaching an absolute zero of temperature, this contribution occurs independently of the presence of matter, or mass-energy, in Space. In other words, not all thermal radiation can be reduced to vibration, rotation and translation (drift motion) of molecules, i.e. to thermomechanical energy, because the properties of pressure and volume that determine temperature and affect matter, appear indeed to a great extent to be independent from matter, a fact which itself is responsible for the observed catastrophic and unexpected phase changes of matter and has required to this day the insufficient explanation offered semi-empirically by the Van der Waals Force Law.

Finally the third subtype may be designated latent massfree energy radiation—since it deploys neither charge, nor thermal or baroscopic effects, and yet it is responsible for 'true latent heat' or for the 'intrinsic potential energy' of a molecule. It is also responsible for the kinetoregenerative phenomenon whereby an electroscope performs a variable charge-mediated work against the local gravitational field.

The common characteristic of all three subtypes of massfree energy radiation is that they share the same nonclassical fine structure, written as follows for any energy unit, where c is any speed of light wave function, and the wavelength λ and wave function W are interconnected as a function of the physical quality of the energy field under consideration:

$$E=\lambda cW$$

In the instance of longitudinal electric radiation, this takes on the directly quantizable form:

$$E=(\lambda_q c)W_v=p_e W_v=(h/\lambda_x)W_v=\int=q_v$$

where W_v is the voltage-equivalent wave function corresponding to V, P_e constitutes the linear momentum corresponding to the conventional q or e, h is the Planck constant, λ_x the Duane-Hunt constant expressed as a wavelength, λ_q is a wavelength constant; and the sign $=\int=$ signifies exact equality between an expression in the conventional dimensions of length, mass and time, and an expression in length and time dimensions alone.

In the instance of massfree thermal radiation (contributing to temperature changes), the transformation obeys Boltzmann's rule (k is now Boltzmann's constant and T is Kelvin-scale temperature):

$$E=\lambda_{n1}cW_{n1}=\lambda_{n1}(\lambda_V\zeta_p)(\lambda_\alpha\zeta_{n1})=\int=kT$$

and in the third instance—of latent massfree radiation, the transformation obeys the rule:

$$E=\lambda_{n1}cW_{n1}=\lambda_{n1}(\lambda_{n1}\zeta_{n1})(\lambda_{n1}f_{n1})=\lambda_{n1}{}^3\zeta_{n1}f_{n1}$$

where ζ and f are frequency functions, f being a specific gravitational frequency term, and f_{n1} being defined as equal to $(\lambda_{n1})^{-0.5}$ $\text{meter}^{0.5}\text{sec}^{-1}$. ζ_{n1} has the value of c/λ_{n1}.

If the electric variant of massfree radiation has a direct quantum equivalence, via the Duane-Hunt Law, none of the three primary aether energy variants possess either the classic form of electromagnetic energy which requires square superimposition of speed of light wave functions c, as c^2, or the quantum form of energy, requiring $E=h\upsilon$. The critical first step in the right direction may well be attributed to Dr. W. Reich, as it regards the fact that massfree energy couples two unequal wave functions, only one of which is electromagnetic and abides by the limit c. We then unravelled the threefold structure described above, and further showed that, in the case of longitudinal electric waves, the postulated equivalence ($q=\lambda_q c$) is merely phenomenological, as these waves are not restricted by the function c in their conveying of electric charge across space. It can further be demonstrated that all blackbody photons are bound by an upper frequency limit ($64*10^{14}$ Hz), above which only ionizing photons are produced, and that all blackbody photons arise precisely from the interaction of massfree electric radiation with molecules of matter (including light leptons), whereby the energy of that radiation is locally converted into photon or electromagnetic radiation. In other words, all nonionizing electromagnetic energy appears to be secondary energy that results locally from the interaction of matter with massfree electric energy. It cannot therefore consist of the primary energy that is present in the vacuum, an energy that is neither virtual nor electromagnetic, but actual and concrete in its electric, thermal and antigravitic manifestations. Lastly, gravitational energy, being either the potential or the kinetic energy responsible for the force of attraction between units of matter, is a manifestation that also requires, much as electromagnetic radiation does, coupling of massfree energy to matter or to mass-energy.

The Tesla coil is a generator of a massfree electric energy flux that it transmits both by conduction through the atmosphere and by conduction through the ground. Tesla thought it did just that, but it has been since regarded instead (because of Maxwell, Hertz and Marconi) as a transmitter of electromagnetic energy. The transmitter operates by a consumption of massbound electric power in the primary, and by induction it generates in the coupled secondary two electric fluxes, one massbound in the coil conductor, and the other massfree in the body of the solenoid. Tesla also proposed and demonstrated a receiver for the massfree energy flux in the form of a second Tesla coil resonant with the first. The receiver coil must be identical and tuned to the transmitter coil; the capacitance of the antenna plate must match that of the transmitter plate; both transmitter and receiver coils must be grounded; and the receiver coil input and output must be unipolar, as if the coil were wired in series.

The generators of massfree energy with which we are concerned provide current pulses associated with a damped wave (DW) oscillation of much higher frequency than the pulse repetition frequency. A particular problem in recovering the massfree energy content of such pulses is provided by the damped wave oscillations. Although in our U.S. Pat. No. 5,416,391 we describe arrangements incorporating split phase motors to recover such energy, their efficiency is a great deal less than what should theoretically be attainable. Other workers such as Tesla and Reich, have encountered the same problem to an even greater degree.

In XIXth century motor engineering terminology, dynamos capable of producing direct current by continuous homopolar induction were known as 'unipolar' generators. The term unipolar induction appears to have originated with W. Weber, to designate homopolar machines where the conductor moves continuously to cut the magnetic lines of one kind of magnetic pole only, and thus require sliding contacts to collect the generated current. Faraday's rotating copper disc apparatus was, in this sense, a homopolar generator when the disc was driven manually, or a homopolar motor when the current was provided to it. Where the rotating conductor continuously cuts the magnetic field of alternatingly opposite magnetic poles, the operation of a machine, whether a generator or a motor, is said to be heteropolar. Unipolar machines went on to have a life of their own in the form of low voltage and high current DC generators—from Faraday, through Plucker, Varley, Siemens, Ferraris, Hummel, to Lord Kelvin, Pancinoti, Tesla and others—almost exclusively in the form of disc dynamos, but some having Wound rotors. In Mordey's alternator, and in so-called 'inductor alternators', however, homopolar generators were employed to obtain alternating currents, with the use of rotors wound back and forth across the field. Use of smooth, unwound rotors in AC induction motors (as opposed to AC synchronous motors, such as hysteresis motors) was a later development than homopolar dynamos. By 1888, Tesla and Ferraris amongst still others, had independently produced rotating magnetic fields in a motor, by employing two separate alternate currents with the same frequency but different phase. Single phase alternate current motors were developed later, and split-phase motors were developed last. Ferraris (Ferraris, G (1888) "Rotazioni elettrodynamiche", Turin Acad, March issue.) proposed the elementary theory of the 2-phase motor, where the current induced in the rotor is proportional to the slip (the difference between the angular velocity of the magnetic field and that of the rotating cylinder), and the power of the motor is proportional to both the slip and the velocity of the rotor.

If an iron rotor is placed within the rotating magnetic field of a 2-phase stator, it will be set in rotation, but not synchronously, given that it is always attracted to the moving magnetic poles with a lag. But if an aluminum or copper rotor is used instead, it becomes 'dragged' around by the rotating stator field because of the eddy currents induced in it. If the aluminum or copper rotor were to rotate synchronously with the stator magnetic field, there would be no induced eddy currents and thus no motor action would result. The motor action depends, in this instance, upon the presence of asynchronous slip, since the function of the latter is to sustain the induction of those currents in the rotor that are responsible for the motor action of the dragged rotor. This then is the origin of the term 'AC drag motors'. Once the drag rotor evolved from a cylinder to a hollow cup, they earned the epithet of 'drag-cup motors'. Later, already in the XXth century, the cups were fitted over a central stator member, and the sleeve rotor 2 phase servomotor was born.

Tesla knew that impulse currents as well as CW sinusoidal currents could be used to drive AC motors. Regarding his invention of an hysteresis motor ('magnetic lag motor', as he called it), he stated: " . . . pulsatory as well as an alternating current might be used to drive the[se] motors . . . " (Martin, TC (1894) "The inventions, researches and writings of Nikola Tesla", Chapter XII, p. 68). In his search for efficient utilization of the high frequency DW impulse currents of his induction coils, Tesla began by employing an AC disc induction motor as shown in FIG. **17** of his famous 1892 address (Tesla, N (1892) "Experiments with alternate currents of high potential and high frequency", in "Nikola Tesla Lectures", 1956, Beograd, pp. L-70–71). This consisted of a copper or aluminum disc mounted vertically along the longitudinal axis of an iron core on which was wound a single motor coil which was series wired to the distal terminal of an induction coil at one end, and to a large suspended and insulated metal plate at the other. What was new about this was the implementation of an AC disc induction motor drive, where the exciting current traveled directly through the winding with just a unipolar connection to the coil secondary (under certain conditions, even the series connection to the plate could be removed, or replaced with a direct connection to the experimenter's body): "What I wish to show you is that this motor rotates with one single connection between it and the generator" (Tesla, N. (1892), op. cit., L-70, Tesla's emphasis). Indeed, he had just made a critical discovery that, unlike in the case of massbound charge where current flow requires depolarization of a bipolar tension, massfree charge engages current flow unipolarly as a mere matter of proper phase synchronization.

Tesla thought that his motor was particularly adequate to respond to windings that had 'high-self-induction', such as a single coil wound on an iron core. The basis of this self-induction is the magnetic reaction of a circuit, or an element of a circuit—an inductor—whereby it chokes, dims or dampens the amplitude of electric waves and retards their phase.

For the motor to respond to still higher frequencies, one needed to wind over the primary motor winding a partial overlap secondary, closed through a capacitor, since "it is not at all easy to obtain rotation with excessive frequencies, as the secondary cuts off almost completely the lines of the primary" (Idem, L-71.).

Tesla stated that "an additional feature of interest about this motor" was that one could run it with a single connection to the earth ground, although in fact one end of the motor primary coil had to remain connected to the large, suspended metal plate, placed so as to receive or be bathed by "an alternating electrostatic field", while the other end was taken to ground. Thus Tesla had an ordinary induction coil that transmitted this "alternating electrostatic field", an untuned Tesla antenna receiving this "field", and a receiver circuit comprising his iron-core wound motor primary, a closely coupled, capacitatively closed secondary, and the coupled nonferromagnetic disc rotor. Eventually, in his power transmission system, he would replace this transmitter with a Tesla coil, and place an identical receiving coil at the receiving end, to tune both systems and bring them into resonance. But his motor remained undeveloped, and so did the entire receiver system.

Tesla returned to this subject a year later: "on a former occasion I have described a simple form of motor comprising a single exciting coil, an iron core and disc" (Tesla, N (1893) "On light and other high frequency phenomena", in "Nikola Tesla Lectures", 1956, Beograd, pp. L-130, and L-131 with respect to FIG. **16**-II). He describes how he developed a variety of ways to operate such AC motors unipolarly from an induction transformer, and as well other arrangements for "operating a certain class of alternating motors founded on the action of currents of differing phase". Here, the connection to the induction transformer is altered so that the motor primary is driven from the coarse secondary of a transformer, whose finer primary is coupled, at one end, directly and with a single wire to the Tesla secondary, and at the other left unconnected. On this occasion, Tesla mentions that such a motor has been called a 'magnetic lag motor', but that this expression (which, incidentally, he had himself applied to his own invention of magnetic hysteresis motors) is objected to by "those who attribute the rotation of the disc to eddy currents when the core is finally subdivided" (Tesla,N (1893), op. cit., p. L-130).

In none of the other motor solutions, 2-phase or split-phase, that he suggests as unipolar couplings to the secondary of an induction coil, does the nonferromagnetic disc rotor motor again figure. But he returns to it a page later, and indirectly so, by first addressing the disadvantages of ferromagnetic rotors: "Very high frequencies are of course not practicable with motors on account of the necessity of employing iron cores. But one may use sudden discharges of low frequency and thus obtain certain advantages of high-frequency currents-without rendering the iron core entirely incapable of following the changes and without entailing a very great expenditure of energy in the core. I have found it quite practicable to operate, with such low frequency disruptive discharges of condensers, alternating-current motors."

In other words—whereas his experiments with constant wave (CW) alternating currents, and as well with high-voltage DW impulses from induction coils, indicated the existence of an upper frequency limit to iron core motor performance, one might employ instead high-current, DW impulses—of high DW frequencies but low impulse rates—to move these motors quite efficiently. Then he adds "A certain class of [AC] motors which I advanced a few years ago, that contain closed secondary circuits, will rotate quite vigorously when the discharges are directed through the exciting coils [emphasis added]. One reason that such a motor operates so well with these discharges is that the difference of phase between the primary and secondary currents is 90 degrees, which is generally not the case with harmonically rising and falling currents of low frequency. It might not be without interest to show an experiment with a simple motor of this kind, inasmuch as it is commonly thought that disruptive discharges are unsuitable for such purposes."

What he proposes next forms the basis of modern residential and industrial AC electric power meters, the AC copper disc motor whose rotor turns on the window of these meters, propelled forward by the supply frequency. But instead of employing any such CW input, Tesla uses the disruptive discharges of condensers, incipiently operating as current rectifiers. With the proper conditions, e.g. correct voltage from the generator, adequate current from the capacitor, optimum capacitance for the firing rate, and tuned spark-gap, to mention a few, Tesla found that the nonferromagnetic disc rotor turned but with considerable effort. But this hardly compared to the results obtained with a high-frequency CW alternator, which could drive the disc "with a much smaller effort". In summary then, Tesla went as far as being the first to devise a motor driven by Tesla waves, that employed a nonferromagnetic rotor, and whose arrangement encompassed both transmitter and receiver circuits. For this purpose, he employed a single phase method in which the signal is fed unipolarly to the winding, placed in series with a plate capacitance.

Tesla also later proposed driving a similar single-phase nonferromagnetic disc motor from bipolar capacitative discharges through an atmospheric spark-gap now placed in parallel with the main motor winding, and again simulating a split-phase by a closely wound secondary that was closed by a capacitance.

As Tesla admits, the results of all his AC eddy current motor solutions were meagre and limited by current and frequency problems. Likewise, the two phase arrangements proposed by Reich for his OR motor, involving a superimposition of the damped waves of a first phase on a fixed continuous wave second phase, require an external power source and a pulse amplifier circuit, and failed to meet Reich's own desiderata.

We have previously proposed the use of squirrel cage motors with capacitative splitting of phase to convert the damped wave (DW) output of plasma pulsers, but once a squirrel cage (SC) is introduced, the dampening effect which the nonferromagnetic copper cage exerts in being dragged by the revolving stator field is counteracted by the ferromagnetic cylinder of laminated iron, in which the copper cage is embedded, working to diminish the slip and bring the rotor to near synchronism. This is, in all likelihood, what limits SC motors to responding to the DC component of the DW impulse, and thus be limited to respond to fluxes of massbound charges. Historically, as we shall see, the obvious advantage of the SC servomotors lay in the fact that, in particular for 2-phase applications, they were far more efficient at performing work without evolution of heat. Indeed, if the eddy currents in the nonferromagnetic rotor are permitted to circulate in nonordered form, the rotor material and stator will heat up rapidly and consume much power in that heating. This is in fact considered to be a weakness of AC nonferromagnetic-rotor induction motors.

SUMMARY OF THE INVENTION

The present invention is concerned with conversion to conventional electrical energy of the variants of massfree energy radiation considered above, referred to for convenience as Tesla waves, massfree thermal radiation and latent massfree radiation. The first variant of such radiation was recognized, generated and at least partially disclosed by Tesla about a hundred years ago, although his work has been widely misinterpreted and also confused with his work on the transmission of radio or electromagnetic waves. The Tesla coil is a convenient generator of such radiation, and is used as such in many of the embodiments of our invention described below, but it should be clearly understood that our invention in its broadest sense is not restricted to the use of such a coil as a source of massfree radiation and any natural or artificial source may be utilized. For example, the sun is a natural source of such radiation, although interaction with the atmosphere means that it is largely unavailable at the earth's surface, limiting applications to locations outside of the earth's atmosphere.

According to the invention, a device for the conversion of massfree radiation (as herein defined) into electrical or mechanical energy comprises a transmitter of massfree electrical radiation having a damped wave component, a receiver of such radiation tuned to resonance with the damped wave frequency of the transmitter, a co-resonant output circuit coupled into and extracting electrical or kinetic energy from the receiver, and at least one of structure defining a transmission cavity between the transmitter and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed plasma discharge device incorporated in the co-resonant output circuit. The output circuit preferably comprises a full wave rectifier presenting a capacitance to the receiver, or an electric motor, preferably a split phase motor, presenting inductance to the receiver. The transmitter and receiver each preferably comprise a Tesla coil and/or an autogenous pulsed abnormal glow discharge device. The transmission cavity is preferably at least partially evacuated, and comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively, the plates being parallel or concentric. The structure defining the cavity may be immersed in ion-containing water. The split-phase motor is preferably an inertially damped AC drag motor.

The invention, and experiments demonstrating its basis, are described further below with reference to the accompanying drawings.

SHORT DESCRIPTION OF THE DRAWINGS

FIG. **1** is a schematic view of a Tesla coil connected to a full-wave rectifier to form an energy conversion device;

FIG. **2** is a schematic view of a Tesla coil connected to a gold leaf electrometer;

FIGS. **3**–**6** show alternative electrometer configurations;

FIGS. **7**–**11** show modifications of the circuit of FIG. **1**;

FIG. **12** shows apparatus for investigating aspects of the experimental results obtained with the foregoing devices;

FIG. **13** is a graph illustrating results obtained from the apparatus of FIG. **12**;

FIGS. **14**–**17** show schematic diagrams of embodiments of energy conversion devices;

FIG. **18** is a diagrammatic cross section of an inertially damped drag cup motor; and

FIG. **19** is a schematic diagram of a further embodiment of energy conversion device incorporating such a motor.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Based upon observations of weight loss in metallic matter as induced by exposure to high frequency alternating electric fields, we developed an experimental method to optimize this weight loss, and from this a device that treats the forces causing weight loss as manifestations of intrinsic potential energy ΔU (or true "latent heat") of the molecules of matter, and converts both "true latent heat" energy present in the neighbourhood of a receiver, and "sensible" heat induced within that receiver, into electric energy that can be employed to drive a motor, flywheel or charge battery supplies.

It is commonly believed that the output of the Tesla coil is ionizing electromagnetic radiation. We have demonstrated that it is not; i.e. that it is neither electromagnetic radiation, nor ionizing electromagnetic radiation. The output of an air cored, sequentially-wound secondary, consists exclusively of electric energy: upon contact with the coil, a massbound AC current can be extracted at the resonant frequency, whilst across a non-sparking gap, massfree AC-like electric wave radiation having the characteristics of longitudinal waves, can be intercepted anywhere in adjacent space. Accordingly, the radiation output from such coils is distinct from electromagnetic radiation.

The basic demonstration that the output of a Tesla coil does not consist of ionizing radiation is that it does not accelerate the spontaneous discharge rate of electroscopes, whether positively or negatively charged. In fact, in its immediate periphery, the coil only accelerates the spontaneous discharge rate of the negatively charged electroscope (i.e. the charge leakage rate), whereas it arrests the discharge of the positively charged electroscope (i.e. the charge seepage rate falls to zero). But this dual effect is not due to any emission of positive ions from the secondary, even if it can positively charge a discharged electroscope brought to its proximity. This charging effect is in fact an artifact, in that metals but not dielectrics are ready to lose their conduction and outer valence band electrons when exposed to the massfree electric radiation of the coil. This is simply demonstrated by the apparatus of FIG. **1**, in which the distal terminal of the secondary winding **6** of a Tesla coil having a primary winding **4** driven by a vibrator **2** is connected to the input of a full-wave voltage wave divider formed by diodes **8** & **10** and reservoir capacitors **12** & **14** (the same reference numerals are used for similar parts in subsequent Figures). If the rectifiers employed are nondoped, the coil appears to only charge the divider at the positive capacitance **10**, but if doped rectifiers are employed, the coil will be observed to charge both capacitances equally. Whereas positive ionizers can charge either doped or undoped dividers positively, no positive ionizer can charge a doped divider negatively, clearly demonstrating that the Tesla coil does not emit positive ions.

The basic demonstration that the output of a Tesla coil is not nonionizing electromagnetic radiation of high frequency, such as optical radiation, or of lower frequency, such as thermal photons, is also a simple one. Placement of a sensitive wide spectrum photoelectric cell (capable of detecting radiation to the limits of vacuum UV), wired in the traditional closed circuit manner from a battery supply, at any distance short of sparking from the distal terminal of the coil will show in the dark that the light output from the coil is negligible. This rules out optical radiation at high frequency. The demonstration that the sensible heat output from the Tesla coil is also negligible will be addressed below.

Our theory proposed the existence of physical processes whereby massfree electric radiation can be converted into electromagnetic radiation. Such a process is at work whenever massfree electric wave radiation interacts with electrons, such as those that remain in the valence bands of atoms. This massfree electric energy interacts with charge carriers, such as electrons, to confer on them an electrokinetic energy which they shed in the form of light whenever that electrokinetic energy is dissociated from those carriers (e.g. by deceleration, collision or friction processes). Such a process is at work to a negligible extent in the coil itself and its usual terminal capacitance, hence the faint glow that can be seen to issue from it, but it can also be greatly amplified in the form of a corona discharge by connecting a large area plate to the output of the secondary, as Tesla himself did in his own experiments, and thus by increasing the capacitance of the coil system. Now, what is interesting in this process is that, in the absence of virtually any I^2R losses at the plate, and if the plate thus introduced is bent at the edges so that it has no pointed edges, or if it is in the form of a bowl, or in any other manner that precludes sparking at edges and specially corners, and thus enhances the corona discharge, any electroscope, whether negatively or positively charged, now brought close to the plate will show a tendency to arrest its spontaneous discharge rate. One might say that this is simply the result obtained in a Faraday cage that disperses charge on its outside and insulates electrically its interior, and indeed if an electroscope is placed inside a Faraday cage no amount of Tesla radiation on the outside of that cage, save direct sparking, adversely affects the leakage or seepage rate of the electroscope. In fact, since the effect of such a cage can be shown to be that of, by itself, inducing arrest of either spontaneous electroscopic discharge, this effect simply remains or is magnified when the cage is bathed by Tesla radiation. However, a cage constitutes an electrically isolated environment, whereas a plate with or without curved or bent edges does not. Furthermore, the change observed in the properties of the output radiation from a Tesla coil when certain metal plates or surfaces are directly connected to the distal terminal of the secondary, takes place whilst the capacitance of the coil is increased by the connected plate, and thus the plate is an electrically active element of the circuit—and hence the opposite of an electrically isolated element.

For a long time we believed that the anomalous cathode reaction forces observed in autoelectronic discharges (atmospheric sparks, autogenous PAGD (pulsed abnormal glow discharge) and vacuum arc discharges) were exclusive to an autoelectronic emission mechanism prompted by a direct potential between discharging electrodes. Sparking driven by AC potentials could sustain the same forces, but their mutual cancellation over time would not deploy a net force. In this sense, when a large gold leaf connected directly to the ground (via a water pipe or any other suitable connection) or to another large area plate suspended at some height above the ground, is vertically placed at a sparking distance above the surface of another plate connected to the secondary of a Tesla coil, one would not expect the AC spark to sustain any net force across the gap between the gold leaf and the plate. In terms of cathode reaction forces, one would expect their cancellation to be simply brought about by the high frequency of the current alternation in the coil, as both leaf and plate would alternate between being the emitting cathode or the receiving anode. However, this is not what is observed—instead, the gold leaf **16** lifts away from the plate **18** (FIG. **2**). Connecting instead the suspended gold leaf to the coil terminal, and the bottom plate to the ground in the same manner as described above, also yields the same result.

Even more curious is the finding that this anomalous reaction force deployed by an alternate current of mass-bound charges in the arc, remains present when the sparking is prevented and instead the corona effect is enhanced (by employing a large plate connected to the distal pole of the secondary, and by employing a distance at which sparking ceases), as if the lift itself were the property of the corona underlying the spark channels and not the property per se of the autoelectronic emission mechanism.

By mounting directly the suspended leaf **16** (41 mg of hammered 99.9996% pure gold) at the end of a long dielectric rod **20** balanced at the center and placed on a light stand over an electronic balance **22**, we sought to determine the observed lift of the leaf as weight lost. Surprisingly, and despite the most apparent lifting motion of the leaf, the balance registered a substantial weight gain, indicating the addition of 1 to 5 mg weight (with the same 14 W input to the vibrator stage), independently of whether the leaf was connected to the terminal of the coil or instead to the earth ground via a water pipe. This suggested to us that, whether formed as a DC or AC spark channel, or whether in the form of a corona discharge, the electric gap develops an expansion force (exactly opposite to a Casimir force) on both electrodes, independently of their polarity, which force is responsible for the observed repulsion. Yet, this expansion goes hand in hand with an increase in their weight such that some other process is at work in that electric gap.

To examine this problem further, we assembled a different experiment where the gold leaf **16** was suspended between two large metal plates **18**, **24** placed 20 cm apart, and the leaf was not electrically connected to them or to any other circuit, while attached to the dielectric rod employed to suspend it over the electronic balance. Given that the leaf is suitably and equally spaced from both plates, there is no arcing between it and either plate. The obvious expectation is that, since the electric field bathing the leaf alternates at high frequency (measured in hundreds of kilohertz), and the corona from both electrodes should equalize and balance any electric wind, no lift should be observed. In fact, no lift is apparent, but a most curious observation is made: depending upon which orientation is employed for the plates, the gold leaf either gains or loses 4–6% of its weight. This gain or loss is registered for as long as the coil is on. If the top plate is grounded and the bottom one connected to the different terminal of the secondary, a gain in weight is observed (FIG. **3**). If the connections are reversed, an equal weight loss is registered (FIG. **4**).

Furthermore, in this last instance, if the grounded plate **24** is entirely removed (FIG. **5**), and only the top plate remains connected to the distal terminal of the secondary, the observed loss of weight continues to occur such that effectively this reaction can be obtained with unipolar electric fields of high frequency, and provides a unidirectional force which, once exerted upon metallic objects bathed by its field, can be made to oppose or favour gravity.

Now, these effects can be greatly magnified, in the order of 10-fold, if the same gold leaf is made part of a simple series floating electric circuit where the leaf functions as a large area plate, and is wired in series with a coil **26** which, for best results, should be wound so as to be of a length resonant with the secondary of the Tesla-type coil employed; and this coil is connected in turn to a point antenna **28** upwardly oriented (FIG. **6**). The entire floating circuit is mounted on the rod **20** and this in turn is mounted over the sensitive balance. If both plates are kept as in FIGS. **3** & **4**, the observed weight loss and weight gain respectively vary between 30 to 95% of the total weight of the leaf. Again the gain or loss of weight is registered for as long as the coil is on.

These anomalous findings suggested that whatever is the nature of the energy responsible for the force observed in that high frequency alternating current gap, any metallic object placed in that gap will experience a force repelling it from the electric ground. This force will be maximal if the gap frequency is tuned to the elementary or molecular structure of the metallic object. If the electric ground is placed opposite the actual plane of the earth ground, that force will act in the direction of gravity. If, instead, the electric ground and the earth ground are made to coincide on the same plane, that force will act opposite the direction of gravity, i.e. will repel the metallic object from the ground.

No such weight alteration was observed with solid dielectrics, for instance with polyethylene and other thermoplastic sheets.

These facts rule out the possibility of a hidden electrostatic attraction force acting between the plate connected to the different terminal of the secondary and the gold leaf. First off, such an attraction would be able to lift entirely the gold leaf, as is easily observed with the unipole of any electrostatic generator operating with a few milliwatts output with either negative or positive polarity; secondly, the same attraction, if it existed and were the product of an electric force, would surely be manifested independently from whether the experimental leaf was metallic or a dielectric (as again is observed with electrostatic generators).

The results suggest therefore that whenever a large plate is connected to a Tesla-type coil, it induces in surrounding matter that is not part of its own circuit, a directional thrust oriented opposite the electric ground and, if the latter coincides with the gravitational ground, a thrust oriented opposite free fall.

When this thrust is made to oppose gravity, we believe that its effect upon the gold leaf can be compared to the lifting power imparted to the water molecule when it transits from the liquid to the vapor state and which is associated with the increase in internal (or intrinsic) potential 'thermal' energy ΔU (See Halliday D & ResnickR (1978) "Physics", Vol. 1, section 22–8, p. 489). The "specific latent heat" of water (m*L) contains indeed both an expression for the sensible radiant thermal work involving volume and pressure relations ($W=P(V_V-V_L)$, where P=1 Atm, and V_V and V_L, respectively, are the molar volumes in the vapor and liquid phases), and an expression for a quantity of "latent" energy (ΔU) which is associated with the molecule in the more rarefied state. Hence, the relation for the latter with respect to water vapor:

$$\Delta U=(mL)-[P(V_V-V_L)]$$

We propose that likewise, if a very small portion of the energy of the massfree electric waves is indirectly transformed by massbound charge carriers on that plate into blackbody photons (once those charge carriers shed their electrokinetic energy), the greater portion of those waves are directly transformed in the space adjacent to that plate into the latent energy equivalent to ΔU for the atoms of the surrounding air, and so on, until this process itself is also occurring for the atoms of that gold leaf, thus inducing their nonelectrical weight loss and suggesting the existence of a nonthermal "antigravitokinetic" energy term heretofore unknown to mankind other than as "latent heat" or "internal potential energy".

From this viewpoint, the energy released by any Tesla-type coil to its surroundings would be tantamount to a radiative injection of "internal potential energy" which would confer on local gas molecules a weight cancellation (a cancellation of gravitational mass occurring in the absence of any cancellation of inertial mass—a process which the inventors theorize is explained by the neutralisation of elementary gravitons), and the same process would be equally at work for metallic solids but not dielectric solids.

Gold vapour also deploys a substantial intrinsic potential energy. With an enthalpy of vaporization on the order of $H_v=324$ kJ mol^{-1}, the molar volumetric work performed by gold vapor at atmospheric pressure at the temperature of vaporization T_v (2,856° C., i.e. 3129 degrees Kelvin) is:

$$W=P\Delta V_{V\text{-}L}=23.58\text{ kJ mol}^{-1}$$

where $\Delta V_{V\text{-}L}=0.2327\text{ m}^{-3}$. The intrinsic potential energy of gold vapor is then given by:

$$\Delta U=H_v-W=300.4\text{ kJ mol}^{-1}$$

i.e. 12.74 times greater than the volumetric work performed during the phase transition.

It is our contention that this intrinsic potential energy, associated with molecules as their "latent heat", has fine structure that in turn is altered if this energy is released from these molecules and fails to gain a "sensible" thermal form. What is suggested is that the fine structure of "latent heat" is not electromagnetic and obeys instead the molecular function:

$$\Delta U/N_A=\lambda_{n2}{}^2cf_{n2}$$

where N_A is Avogadro's number, the wavelength denoted as λ_{n2} is the wavelength-equivalent of the mass of the molecule to which the "latent heat" is associated, obtained by a conversion method proposed in these inventors' theory, and the frequency term f is a nonelectromagnetic frequency term, specifically in this case a gravitational frequency function. Employing the conversion of Joules into m^3 sec^{-2} proposed by these inventors as being exactly 1 J=10N_Am^3 sec^{-2}, and putting the wavelength λ_{n2} down as the wavelength-equivalent of the mass of the gold atom, λ_{Au}, at 1.9698 m, that frequency term f_{n2} can be obtained as being equal to 2.6*10^{-3} sec^{-1}. According to the present inventors' theory, the wavefunction c constitutive of the fine structure of "latent heat" associated with molecules of matter, carries the same wavelength λ_{Au} and its frequency is given in the usual manner by c/λ_{Au}=1.52*10^8 sec^{-1}. The resultant frequency for the non-Planckian unit quantum of "latent energy" associated with each gold atom at the vaporization temperature is then obtained by the geometric mean of the two synchronous frequency terms:

$$[(c/\lambda_{Au})f_{n2}]^{0.5}=624\text{ Hz}$$

However, this is the signature of that intrinsic potential energy when associated with that gold atom at its vaporization temperature. It is not the signature of the energy quantum itself if it is released from that molecule, nor prior to being absorbed (i.e. in transit), at that same temperature. The fine structure of the same non-Planckian "latent" energy quantum varies to encompass different determinations of the constituent wavelength and frequency functions. The basic relation for the determination of the wavelength of a "latent thermal" energy quantum not associated with matter, but corresponding to one that is, is:

$$\lambda_{n1}=[\Delta U/N_A)/c]^{0.666}\text{ meters}^{-0.333}\text{ seconds}^{0.666}$$

which gives 0.046478 m for the unbound equivalent of the "latent heat" unit quantum of vaporization associated with the gold atom at one atmosphere. The fine structure of the free quantum is still parallel, as given by:

$$\Delta U/N_A=\lambda_{n1}{}^2cf_{n1}$$

but now notice how the frequency terms have changed value, with the f_{n1} function having the value 4.65 sec^{-1} and c/λ_{n1} yielding 6.48*10^9 sec^{-1}. The geometric mean of the superimposition of the two frequencies is then—

$$[(c/\lambda_{n1})f_{n1}]^{0.5}=173.7\text{ KHz}$$

We contend that it is at this frequency that the atoms of gold vapor absorb "latent heat".

However, this is just the overall scenario of what happens at the temperature of vaporization of gold. But at room temperature (e.g. 293 degrees Kelvin), and with respect to processes where there is no sublimation of the atoms of that gold leaf under way (and indeed, once the coil is turned off, the leaf returns to its normal weight), one must infer to a different phase of matter what portion of "latent heat" energy, if any, do the atoms of gold hold in the solid phase lattice. Assuming the same proportionality between the "sensible" and "latent" thermal energy terms for atoms of gold at room temperature, where the unit thermal energy is N_A kT=2.436 kJ mol^{-1}, the gold atom could absorb up to 12.74 times, we speculate, the value of this "sensible" thermal energy, and thus hold N_A kT=31.053 kJ more energy in its own micro-atmosphere.

If this speculation is correct, and employing the above novel methodology, then the mean geometric frequency of the maximal "latent heat" energy quantum of a gold atom at room temperature would be 538 KHz (versus 174 KHz at the vaporization temperature), and once absorbed its mean frequency mode would abate to 201.5 Hz (versus 630 Hz once the atom has vaporized).

To test this hypothesis we employed two different Tesla-type coils having output frequencies of 200 KHz and 394 KHz. The circuit tested was that shown in FIG. **6**, and both coils were operated at 50 KV outputs. Whereas the former coil, closer to the 174 KHz marker, could only systematically produce 10–11 mg of weight cancellation in the gold leaf of the floating circuit, the second coil, closer to the speculated 538 KHz marker, could produce 15–35 mg of weight cancellation in the same gold leaf. The empirical results appear therefore to suggest that our speculation may well be a valid one.

The above-mentioned full wave divider (see FIG. **1**) can be easily coupled to our autogenous pulsed abnormal glow discharge technology as described in our U.S. Pat. No. 5,416,391 to form an alternative source of direct current, ultimately powered by Tesla waves, and such a drive can equally be applied to any other vacuum device that can sustain endogenous oscillatory discharges, whether in the PAGD regime or any other pulsatory regime. For the purposes of experimental and visual determination of power outputs from the divider in question, we have utilized either 2 Torr vacuum tubes operating in the high-current PAGD regime, or 20–100 Torr spark tubes requiring high voltages (2 to 10 KV) for their spark breakdown. As taught in the above U.S. Patent, the output from the full wave voltage divider can be assessed by the energy spent in driving the tube and the motor, whose rotary speed is proportional, within the limits chosen, to the power input.

Two separate sets of experiments set forth in Table I below showed that direct connection of the wave divider to the distal terminal of the coil (set constantly at 6 clicks on the vibrator stage) (FIG. **1**) or to the same terminal but across a large (2 or 3 square feet) plate **30** that increased the capacitance of the secondary (FIG. **7**), presented the same power output in either case (the effect of the plate is to lower the voltage of the output proportional to the increase in current). A substantial increase in power output through the divider is observed only when an identically wound Tesla coil is connected in reverse (FIG. **8**) with the non-common end of its winding **4** not connected, in order to obtain a condition of resonance, and this observed increase is further augmented by now interposing either of the metal plates **18**, **24** between the two chirally connected and identical coils (FIG. **9**). The increase in plate area appears to have the effect of increasing the output for as long as the plate is isolated between the two chiral image coils. Throughout these experiments the input power to the vibrator was fixed at 14 W (60 Hz AC).

TABLE 1

Status	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM
Expt A		
Tesla coil (TC) to divider	2.6	582.5 ± 3.9 (n = 4)
TC to inverted TC, to divider	4.4	621 7.6 (n = 4)
TC to 2 ft^2 plate, to inverted TC, to divider	5	775.25 ± 23.6 (n = 4)
Expt B		
Tesla coil (TC) to divider	2.2	613 ± 5.6 (n = 12)
TC to 3 ft^2 plate, to divider	2.3	605 ± 2.6 (n = 12)
TC to inverted TC, to divider	2.3	722 ± 5.7 (n = 12)
TC to 3 ft^2 plate, to inverted TC, to divider	4.2	877.6 ± 6.5 (n = 12)

In our loss of weight experiments described above, we noted that the phenomenon of weight loss by a metallic body placed in proximity of the coil output continued to be observed when only the plate connected to the distal pole of the secondary was retained. The leaf, although not part of the circuit of the secondary, could however be seen as part of a circuit for the capture of ambient radiant energy, specifically that generated by the coil and, as well, that also possibly picked up, in the process, from other ambient sources. To determine whether the last consideration is a possibility at all, or whether the energy picked up by an analogue of our metallic body or gold leaf in the experiments described above, is entirely a byproduct of the energy transmitted by the plate connected to the distal pole of the secondary, we next determined what would happen if the pick-up for the full wave-divider were placed not at the output from the secondary coil, but from an in all respects identical plate (the Receiver plate R, as opposed to the Transmitter plate T) placed a distance away from, and above, the first one. In other words, the gold leaf is replaced by a receiver plate, and this carries an attached test circuit identical to the test circuit employed to assess directly the coil output.

As shown in Table 2 below, the results of the experiment show that there is no loss of energy picked up at the R plate (FIG. **10**) when compared to the most favourable situation involving the plate **30** (FIG. **9**) interposed between the chirally connected coils. This observation is however not always the case. For best results one should employ iron, gold or silver plates placed parallel to the horizon, with the T plate underneath the R plate. In fact, if one employs instead aluminum plates and suspends these vertically, one can consistently register a loss of output at the divider when changing the divider input from the T to the R plates.

If however the plate R is connected in turn to a second identical coil, also wired in reverse, and this second coil in turn serves as input to the full wave divider (FIG. **11**), then a most curious occurrence takes place—the power output increases considerably (see Table 2), as if the divider circuit had undergone an energy injection not present at the source. Note that the circuits are in fact resonant, but the energy injection contributing nearly 60–66% (for both plate areas in the previous experiment) of the input that we refer to, is not caused by inductive resonance, since the effect of resonance can be ascribed to the set-up described in FIG. **9**. The distance between the plates, as well as their orientation with respect to the local horizon system of the observer also appear to matter, best results being achieved at optimal distances (e.g. for 2 square feet plates the best gap, at 43% RH and room temperature, was at least 6 inches).

TABLE 2

Status	T R distance	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM

R plate to divider	8"	4.0	783.1 ± 11.3 (n = 12)
R plate to inverted TC, to divider	8"	5.1	1005.7 ± 6 (n = 12)

We tested the possibility that environmental heat produced by operation of the coil might be the source of the injected energy, the plate of the second system acting possibly as collector for the heat present in the gap. As it turned out, experiments showed repeatedly that in the gap between the T and R plates there was no significant thermal radiation propagating between one and the other. The more illustrative experiments are those in which we identified where the sensible thermal energy appears, and which involved coupling two cavities: the Transmitter-Receiver gap between plates T and R, and a Faraday cage enclosure **34** (see FIG. **12**). The first cavity appears to be much like that of a capacitor: the two identical parallel plates are surrounded by a thick dielectric insulator **32**, and a thermometer T**2** is inserted half-way through it. A thermometer T**1** is also affixed to the T plate, to read its temperature. The second cavity is a simple metal cage, also insulated, with a thermometer T**3** inserted 2 cm into its top. 2–4 cm above the top of the cage there is placed a fourth thermometer T**4**, within an insulated cylinder. If the TC is a source of thermal energy (e.g. IR radiation, microwaves, etc.) we would expect the T plate to be the hottest element from which, by radiation, thermal energy would reach the middle of the first cavity making the next thermometer T**2** second hottest, and that the third thermometer T**3** inside the second cavity, even if it might initially be slightly warmer than the other two, would, over time, become comparatively cooler than either one of the other two thermometers, despite the fact that the rising heat would still be seen to warm it up over time. One would expect a similar outcome for the fourth thermometer T**4**, above the cage. As shown by FIG. **13**, where only the temperature differences $(\Delta T^\circ - T_c^\circ)$ between the experimental thermometers and the control thermometer reading the air temperature T_c° of the laboratory are shown, the surface of the T plate warms up by 0.1° C. at 3' after initiation of the run (closed squares), whereas in the space of the T/R gap a diminutive warming, by 0.05° C., is registered after 10' (open circles). Conversely, the temperature inside the cage, at the top (shaded circles) rises by 0.1° C. also by the third minute, and the temperature above the cage itself (shaded squares) rises by a much greater difference of 0.35° C., which remains stable after the eighth minute.

These results show that it is not sensible heat that radiates from the T plate. Rather, some other form of radiation traverses these cavities to generate sensible heat at their metallic boundaries, such that more heat is generated above the R plate (inside the cage) and again above the third plate, i.e. above the top of the cage, than is generated in the T/R gap, i.e. proximally to the T plate. This clearly shows that the Tesla coil is not a significant source of thermal radiation, and that sensible heat can be detected inside and atop the Faraday cage only as a further transformation of the radiant energy transmitted across the T/R cavity.

The same experiment also illustrates that, whatever is the nature of the additional environmental energy being injected at the surface of R plate (as shown by Table 2 results above), it is most likely not thermal radiation, at least not energy in the form of sensible heat. And whatever is the nature of this ambient radiant energy being mobilized by the electric radiant energy transmitted from the T plate, it can produce significant heat inside an enclosure contiguous with plate R.

Since we also know experimentally that this observation of an ambient energy injection at the R plate or R cage depends upon relative humidity, being most easily observable when the latter is low (<50% RH), and being virtually impossible to observe when air is saturated with water vapor, we can infer that water vapor is a good absorber of the electric massfree radiant energy emitted from the T plate. This strongly suggests that this absorption process is tantamount to increasing the potential intrinsic energy ΔU of the water vapor molecules adjacent to the T plate. In the absence of significant quantities of water vapor, when the atmosphere is dry, one may speculate that this absorption process is replaced by what one presumes is a parallel process involving the various gaseous molecules of air. However, either because the air molecules involve molecular species that readily give off this potential energy, as one might speculate is the case with molecular oxygen, hydrogen and nitrogen, or because the air molecules absorb far less "latent" energy (as appears to be the case with inert gases), and therefore there is more of it in the molecularly unbound state (as we explicitly propose as a possibility) and thus available for absorption by the appropriately tuned receiver, the increased ΔU of air molecules conferred by the absorption of the massfree electric radiation in the T/R gap is transferred to the R conductor together with the latent energy which those molecules already possessed before entering that gap. Hence the energy injection and its dependency upon the partial pressure of water vapor, which absconds instead with this "latent" energy and succeeds in withholding it from transmission to the R plate.

If the T/R gap can mobilize ambient energy which is neither electromagnetic nor thermal in nature, but which "latent" energy becomes injected into the divider circuit in electric form, the heat (i.e. sensible thermal energy) produced inside and atop the cage can also be mobilized electrically as input into the divider circuit. The obvious place to look for the emplacement of the cool junction that could convert sensible heat into electrokinetic energy of massbound charges is at the top of the cage, where it is warmest (See top curve of FIG. **13** in shaded squares). This is clearly observed from the results shown in Table 3 below, where the initial temperature difference between the top of the box and the T plate surface was 0.5° C., and the top of the box temperature rose by 0.2° C. after 2.5 minutes when the divider was connected at the junction, versus 0.35° C. when it was not (and the transmitter coil was on).

TABLE 3

Status 3 ft^2 plates	TR distance inches	Pulse rate PPS	Motor rotation RPM, M ± SEM(n = 12)
TC to T plate, to divider	NA	4.2	877.6 ± 6.5
R plate to inverted TC, to divider	6"	5.1	1009.2 ± 4
Top of naked R plate/cage to divider	6"	5.4	1047.1 ± 5.7
Top of insulated R plate/cage exposed to sun, to divider	6"	6.1	1072.4 ± 8.7

For the run performed with the naked R cage, the temperature directly above the top of the cage was 24.3° C., at the outset, versus the control room temperature of 23.9° C. For the run performed with the insulated R cage exposed directly to the sun at midday, on a cool and clear August day, the temperature directly above the top of the cage was 33° C., versus the control air temperature of 18.4° C. The temperature of the cool junction at the top of the cage was 31.9° C. while the run was performed.

It is apparent from the data of Table 3 how a second injection of energy has occurred in the apparatus. If, within the T/R gap, the energy injected appears to be on the order of absorption of "latent heat", at the top of the cage cavity, at the cool junction, the injection is one of radiant "sensible" heat. Moreover, this secondary energy addition could be further enhanced by placing strong insulation around the whole apparatus or the cage itself, and further so, by exposing the whole apparatus to solar radiation.

We next turned our attention to the T/R gap cavity with the intention of determining whether atmospheric conditions or vacua yield the same or different results. We could not, of course, test the same large area plates as have been employed for the studies undertaken at atmospheric pressures. For the present purpose we employed instead large area electrodes (ca 0.2 ft^2) made of high grade stainless steel or even aluminum. Preliminary results showed that these T/R gap tubes, when coupled to the divider circuit, yielded faster pulse rates in the secondary circuit when evacuated than at atmospheric pressure. The strength of the corona discharge also intensified, as it eventually became replaced by a normal glow discharge. For purposes of improved spatial capture of (1) the electric massfree energy radiated from the T electrode and (2) the non-radiant latent thermal energy mobilized by it to be collected electrically at the R plate, an axial cylindrical T electrode was inserted inside a larger concentric cylinder or between two common plates of large surface area (e.g. >100 cm^2) functioning as the R electrode(s), in a dielectric container suitable for evacuation (glass, polycarbonate), at a typical distance of at least 3 cm between electrodes, and the entire device was tested at different pressures. The secondary circuit connected downstream from the full wave divider was as shown in FIG. **14** (employing an autogenous pulsed abnormal glow discharge, or PAGD, converter circuit), with the PAGD reactor 36 set at 10 Torr (in light of the high-voltage input, which varied between 1500 and 3200V) and gave the results presented in Table 4 below. We should remark also that these pulses charged the charge pack CP through the coupling capacitors **38**, bridge rectifier **40** and reservoir capacitors **42**, and blocking diodes **44**, as expected from the prior art represented by our patents related to PAGD devices.

TABLE 4

T/R tube Pressure (Torr)	Pulse rate (PPS)
760	0.376
0.025	0.513

The effect of the vacuum in the T/R gap tube seems to be dual. By transforming the corona discharge into a normal glow discharge, it increases the local production of photons (probably associated to the formation and discharge of metastable states in the plasma), and at the same time, increases the pulse rate in the output circuit and thus, in all probability, the energy injected in the T/R gap cavity. But this did not yet permit us to confirm whether or not it is "latent heat" energy of the plasma molecules which is being tapped at the receiver plate, even if it be plausible in principle that plasmas may effect more efficient transfer of "latent heat" to tuned receivers than atmospheric gases.

The vacuum dependency of the pulse rate of the PAGD reactor employed as example in the secondary circuit downstream from the divider is also rather well marked, with the fastest pulse rates being registered at 1 Torr for the sample run shown in Table 5 below.

TABLE 5

T/R tube Pressure (Torr)	Pulse rate (PPS)	PAGD Reactor Pressure (Torr)	Voltage (across divider)
0.025	0.115	90	4.5 kV
0.025	0.1553	75	3.5 kV
0.025	0.183	60	3.3 kV
0.025	0.291	30	
0.025	0.513	15	1.6 kV
0.025	0.602	10	1.4 kV
0.025	2.9	2	0.53 kV
0.025	4.1	1	0.45 kV

It is worth noting here that the illustrated polarity of the wiring of the PAGD reactor tube, as shown in FIG. **14**, is best for purposes of sustaining regular autoelectronic emission at high voltage. The reverse configuration, with the center electrode negative and the plates positive favours instead heating of the cathode and a lapse into a normal glow discharge.

We tested a similar arrangement to that shown in FIG. **14** above, but with a PAGD motor circuit (see our U.S. Pat. No. 5,416,391). A split phase motor **44** replaces the rectifier and charge pack, and the PAGD reactor is operated at the same pressure of 15 Torr, as shown in FIG. **15**. The T/R gap tube tested had a longer plate distance (2"), with one plate now functioning as Transmitter and the other as Receiver. Note also the different wiring of the PAGD reactor. The results, as shown below in Table 6, present pulse per second (PPS) and motor revolutions per minute (RPM) curve trends that appear to be analogous and parallel to the well-known Paschen curves for breakdown voltage in vacuum—such that the T/R gap performs better either in the atmospheric corona discharge mode, or in the high vacuum normal glow discharge (NGD) mode, than in the low breakdown voltage range of the curve where the discharge forms a narrow channel and takes on the appearance of an "aurora" transitional region discharge (TRD).

TABLE 6

T/R tube Pressure (Torr)	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM (n = 17)	Discharge Type
760	2.8	751.2 ± 7.1	Corona
100	2.1	611.5 ± 5.1	TRD
20	2.4	701.9 ± 4.6	TRD
0.006	2.8	748.4 ± 9.3	NGD
0.003	3.0	819.4 ± 6.3	NGD

These results suggest that plasmas with high lateral dispersion, i.e. formed over large electrode areas (e.g. corona and NGD plasmas) and thus devoid of pinch, are more likely to mobilize electrically the intrinsic potential energy of the molecular charges than pinch plasmas appear to be able to do (e.g. TRD plasmas). Apparently also, the greater the vacuum drawn from the T/R gap cavity, the more efficient does the transfer of this intrinsic potential energy, ie the massbound latent heat, to the electrokinetic energy of the charges circulating in the receiver circuit become. At about $6*10^{-2}$ Torr, this transfer in vacuo is comparable to that observed under atmospheric conditions and thus for a much greater density of molecules.

We investigated whether it Is possible to tap the latent heat energy of water molecules. It is possible that in the vapour phase they can effectively hold onto their latent energy—but once closely packed in liquid phase could they give off some of it? To test this hypothesis we immersed the T/R gap in a glass water tank. The motor employed for these tests was a high-speed 2 phase drag-cup motor (see FIG. **18** and associated description), wired in split-phase with two identical phase windings capacitatively balanced, and the galvanized iron plates had one foot square areas. The results are shown in Table 7 below, and clearly indicate that it is possible to tap—within the T/R cavity—the 'latent heat' of water in the liquid phase. As observed, immersion of the T/R cavity in water increased the motor output speed 22% (=12,117/9888)*100). This corresponds to a 50% increase in power output, from 18 W at 9888 rpm to 27 W at 12,117 rpm:

TABLE 7

	Pulse rate PPS	Motor rotation RPM M ± SEM	T/R distance cm
Direct from TC	0.3	8076 ± 89.3	NA
TC to T plate	0.5	9888 ± 78.7	NA
R plate	2.75	12117 ± 29.8	30
R plate	2.9	12203 ± 55.9	60

Thus the use of ion-containing water or other ion-containing aqueous liquid in the cavity promotes long distance propagation and a greater injection of latent and thermal energies in the receiver circuit. Such a result is not achieved if the cavity is filled with deionised water.

The preceding results lead therefore to the design of a presently preferred apparatus, based on these findings, for the conversion of massfree electric energy, "latent heat" energy and "sensible" heat energy into conventional electric energy, as shown in FIG. **16**, which integrates all the separate findings and improvements. The winding **6** of the Tesla coil at the bottom is driven in the usual manner employing a vibrator stage **2** to pulse the primary coil **4**. The distal pole of the secondary **6** is then connected to a circular metal plate T which is one end of an evacuated cylindrical cavity, connected to a vacuum pump or sealed at a desired pressure, or which forms a still containing water or other aqueous solution or liquid. This cavity constitutes the transmitter/receiver gap, and is therefore bounded by a dielectric envelope and wall structure **32**, with the circular receiver plate R as its top surface. In turn this plate R serves as the base of a conical Faraday cage **34**, preferably air-tight and at atmospheric pressure, but which could also be subject to evacuation, which conical structure carries at its apex provisions for a cold junction **45** and any possible enhancement of the same junction by surface application of different metallic conductors that may optimize the Peltier-Seebeck effect. The output from the cold junction where sensible thermal energy is added to the electrokinetic energy of charge carriers, is also the input to the distal end of the winding **6** of the chiral coil arrangement that sustains resonant capture of all three energy flows ((1) massfree electric waves of a longitudinal nature, (2) true "latent heat" or the intrinsic (thermal) potential energy, and (3) the thermokinetic energy of molecules, (i.e. "sensible" heat) and, placed in series with the input of the full wave divider **8**, **10**, feeds the circuit output from the series capacitors **12**, **14** grounded at their common tap. In the T/R gap, the transmitted electric longitudinal wave energy is captured along with any intrinsic potential energy shed by molecules caught in the field. Within the R element, expanded into an enclosure that guides "sensible" radiant heat, the latter is generated and then recaptured at the cold junction.

The apparatus consisting of the cylindrical T/R gap cavity and the contiguous conical cage is then preferably finished in gloss white and cylindrically enveloped within a matte black container **46** by effective thermal insulation **48**, the latter terminating at the height of the bottom disc T. Apparatus (not shown) may be provided to move the plate T vertically to adjust the T/R gap.

Another alternative embodiment of the apparatus is shown in FIG. **17**. Here the circuit driving the apparatus is as we have set forth in our prior patents, which employs an autogenous pulsed abnormal glow discharge tube **50** in the configuration shown, supplied by a battery pack DP through blocking diodes **52** and an RC circuit formed by resistor **54** and capacitor **56** to drive the primary 2 of a first Tesla coil to obtain at the distal pole of the secondary **6** the energy to be injected to plate T in the form of a central electrode of a coaxial vacuum chamber (sealed or not), of which the cylindrical metallic envelope forms the receiver plate R, the latter being placed centrally inside the conical cage **34** and contiguous with its walls and base. The top and bottom of the coaxial chamber carries suitable insulating discs, preferably with O-ring type fittings. Again, the apparatus is enclosed in insulation within a cylindrical container **46**, and the input into the capture circuit driven from the full wave divider is taken from the cold junction **45** at the apex of the air-tight cage. The output circuit is similar to that of FIG. **15**.

We have found however that even when the component values in the motor driver and motor circuits are carefully selected so that these circuits are co-resonant with the damped wave (DW) component of the motor driver pulses, the motor power output falls well short of that which should theoretically be attainable. In an endeavour to meet this problem, we replaced the squirrel cage type induction motor **44** by a drag cup motor of type KS 8624 from Western Electric in the expectation that the low inertia non-magnetic rotor would allow better response to the DW component. This motor is similar to one of the types used by Reich in his experiments. Although results were much improved they still fell short of expectations. Replacement of this motor by an inertially damped motor of type KS 9303, also from Western Electric, provided much better results as discussed below.

Fundamentally, the difficulties we encountered stemmed from the inability of motor couplings to respond efficiently and smoothly, and at the same time, to the pulse and wave components of DW impulses: that is, simultaneously to the high-intensity peak current pulses (the front end event), the DC-like component, and to the damped wave trains these cause, i.e. the pulse tails (or back end event) or AC-like component. This difficulty is present even when we just seek to run induction motors from the DW impulses of a Tesla coil, the very difficulty that led Tesla to abandon his project of driving a nonferromagnetic disc rotor mounted on an iron core bar stator with damped waves.

We believe that the key to the capture of the massfree energy flux output in electric form by Tesla transmitters, including any injected latent or thermal energy that have undergone conversion into electrical energy is to employ the tuned, unipolar, Y-fed, PAGD-plasma pulser driven split-phase motor drive we have invented (U.S. Pat. No. 5,416,391) in conjunction with an inertially damped AC servomotor-generator (see FIG. **18**): this has a motor shaft **64** which couples a drag-cup motor rotor **60**, preferably of aluminum, silver, gold or molybdenum, directly to a drag-cup generator rotor **62** that drives a permanent magnet (PM) flywheel **66**, freely rotatable in bearings **67**, that provides inertial damping. The shaft **64**, journalled by bearings **61** in the casing of the motor **44**, provides a power output through optional gearing **68**. The phase windings of the motor **44** are wound on a stator core **70** having concentric elements between which the rotor or cup **60** rotates. This structure makes it ideal for the capture of the DW impulses, whether sourced in the transmitter, amplified in the T/R cavity or sourced in the plasma pulser, all in synchrony. Effectively the motor couples the damping action of the drag-cup sleeve motor rotor, which action, as we have already found for the KS-8624 motors, is quite effective at absorbing the front-end DC-like event, with the inertial damping of the PM flywheel upon the drag-cup sleeve generator rotor, that in turn is quite efficient at absorbing the back-end AC-like wavetrain event.

The KS-9154 motor used by Reich was not an inertial damped AC drag-cup servomotor-generator. Had Reich succeeded in overcoming the limitations of his 2-phase OR Motor solution, as we have now shown it is possible to do—by applying the Function Y circuit to the PAGD split-phase motor drive which we invented, his motor would have suffered the same limitations which we encountered with the KS 8624 motor.

Any motor, by itself, has an internal or inherent damping whereby the acceleration only vanishes when the rotor is running at constant speed. For motors that operate on the basis of the drag principle, where the asynchronous slip is actually constitutive of the motor action, by inducing eddy currents in the rotor, the inherent damping is always more pronounced than for other induction motors. The damping or braking torque is produced when a constant current flows through a rotating drag disc or cup.

Aside from this inherent braking, dampers can also be applied to servomotors to further stabilize their rotation. They absorb energy, and the power output and torque of the motor is thereby reduced. Optimal operation of servomotors requires both rapid response on the part of the rotor to changes in the variable or control phase, and a stable response that is free from oscillation, cogging and overshooting. The rapid response is assured by employing low inertia rotors, such as drag-cups or cast alloy squirrel cages, and the overshooting and oscillation are reduced to a minimum by damping or a retarding torque that increases with increasing motor speed. Typically, in a viscous-damped servomotor, the damper is a drag-cup generator mounted rigidly on the shaft of the motor rotor, and the generator drag-cup rotates against the stator field of a static permanent magnet field. The generator develops a retarding torque directly proportional to speed, and the energy absorbed by the damper is proportional to speed squared. The damping can be adjusted and, as it increases, the same amount of input power yields lower torque and motor speeds. Inertial-damped servomotors differ from viscous damped motors in that the permanent magnet stator of the drag-cup generator is now mounted in its own bearings, either in the motor shaft or on a separate aligned shaft, forming a high-inertia flywheel. This means that, whereas the motor rotor always experiences a viscous damping in viscous-damped servomotors, in inertial-damped servomotors the drag cup motor rotor only experiences a viscous damping while accelerating the flywheel, with the damping torque always opposing any change in rotor speed. Once the flywheel rotates synchronously with the rotor, all damping ceases. Note that this viscous damping is carried out via the coupling of the drag-cup generator rotor, rigidly affixed to the motor rotor, to the PM flywheel, so that their relative motion generates the viscous torque proportional to the relative velocity. Use of drag-cup sleeve rotors in inertially damped servomotors was largely supplanted by squirrel cage rotors once the latter became produced as cast alloy rotors. Since inertially damped motors can be used in open and closed-loop servo applications, and present better stability—even in the presence of nonlinearities—and higher velocity characteristics than other induction motors do (Diamond, A (1965) "Inertially damped servo motors, performance analysis", Electro-Technology, 7:28–32.), they have been employed in antenna tracking systems, stable inertial-guidance platforms, analog to digital converters, tachometers and torque tables. The typical operation of an inertially damped servomotor is as follows: with the reference phase fully excited, the motor rotor—fixedly linked to the generator rotor, as well as the flywheel, remain immobile; once power is applied to the control phase, the motor rotor immediately responds but the flywheel remains at rest. However, as the drag-cup generator **62** is forced to move through the permanent magnetic field of the flywheel, it creates a drag torque that slows down the attached motor rotor proportionally to the acceleration that it imparts to the flywheel that it now sets into motion, thus creating the viscous damper. As the flywheel accelerates, the relative speed of the motor with respect to the flywheel, as well as the damping torque, decrease until both motor and flywheel rotate synchronously and no damping torque is exercised—at which point the drag on the motor cup exerted by the generator cup is negligible. The KS-9303 motor is an inertial damped servomotor but is differentiated with respect to other inertially damped motors, in that (1) it employs a drag-cup sleeve motor rotor made of aluminum, very much like that of the KS-8624, but with slightly altered dimensions and with a shaft extension for the drag-cup copper generator rotor, and (2) the moving flywheel structure was journalled on a separate, fixed shaft, as already described with reference to FIG. **18**. Now, in principle, even application of minimal damping decreases motor efficiency, resulting in diminished torque and speed. Whether the inertial-damped motor has a drag-cup rotor, a sleeve rotor or a squirrel cage rotor, the damping increases the rotor slip. Laithwaite considers drag-cup motors as being "dynamically inferior to their cage counterparts" (Laithwaite, ER

(1957) "Induction machines for special purposes", London, England, p. 323.). If we now add a viscous damping and retarding torque, we should not be able to get much more than a 55% efficiency in the best of conditions. On the other hand, the inertial damping arrangement described will only abstract or supply energy when the motor rotor is accelerating or decelerating relative to the flywheel.

These drag-cup motors, whether inertially damped or not, develop a constant torque at constant rpm for a given supply frequency and a suitable phase shift capacitance. For each frequency the motors respond to, there is an optimum resonant split-phase capacitance, but other values nearby are still suited for operation, and for each value of capacitance, there is an optimal frequency the motors respond to. For example the KS-8624 motor responds best at 450 Hz when a 1 μF capacitance is employed, responds best at 250 Hz when a capacitance of 10 μF is employed, and responds best at 60 Hz, when a capacitance of 100 μF is employed. As the capacitance increases, the resonant CW frequency of the motor is displaced to lower values. If we fix the capacitance at a value (e.g. 10 μF) suitable for testing the frequency response at a fixed voltage of 12 VAC, the observed result for both the KS-8624 and KS-9303 motors show a response distribution of the motor rotary velocity that has an identical peak at 250 Hz for both motors, with the response decreasing to zero smoothly on both sides of the peak. These results indicate that, when wired as a split-phase motor, the motor rotary velocity varies not as a function of voltage or current, but as a function of frequency when the phase-splitting capacitance is fixed within a suitable range, there being an optimal frequency mode for each value of suitable capacitance, with lower values of capacitance favouring higher frequency modes. For a given frequency and capacitance, the motor rotary velocity remains essentially constant and independent from voltage and current input, and thus at a plateau. Torque, in the same circuit arrangement, follows exactly the same pattern as rotary velocity, as a function of input frequency at a fixed potential. Torque is linearly proportional to rpm in these motors when they are split-phase wired, and rpm linearly proportional to CW frequency, which makes them ideal for experimentation and determination of power output computations. Moreover, since these are drag machines, the slip itself determines the rotor currents and these are susceptible of tuning such that their retardation and relative position in the field can find resonant modes for varying CW frequency and capacitance.

In the circuit of FIG. **17** when using the KS 9303 motor, the inertial damping of the flywheel coupling retards the motor rotor currents sufficiently to allow them to build up torque, with the entire motor assembly serving as the preferred sink for all of the energy, massfree and massbound, captured by the receiving coil circuit with a drawing action established by the motor on the circuit, and providing satisfactory absorption by an inertial damper of the combined, synchronized, damped wave impulses, those occurring at a low frequency as a result of the firing of the PAGD reactor, and those occurring at a higher superimposed frequency—sourced in the transmitter circuit and picked-up by the receiver plate and coil. The action of each DW impulse train itself comports two different events, the DC-like auto-electronic-like discontinuity that sets the motor into action and initiates the rotor currents, and the AC-like damped wavetrain that supports the consistency of those rotors. The concentration of current required to kickstart the motor is provided by the DW impulses of the PAGD reactor, whereas, once the motor is in motion, and particularly, once it is stabilized by the flywheel, the cumulative action of the higher frequency DW impulses makes itself felt by accelerating the rotor to an optimum rotary velocity.

For the next series of tests we employed the basic circuit diagram of the improved motor shown in FIG. **19**. The transmission station is the typical Tesla transmitter with a line-fed, 60 Hz vibrator stage. At the line input to the first stage, we place a calibrated AC wattmeter (Weston Model 432), and a Beckman 330B rms ammeter in series with the hot lead, we set the vibrator stage for 41 clicks, consuming between 28.5 and 35 W, as depending upon circumstances yet to be narrated. This consumption was confirmed by driving the coil from an inverter powered by a 12 volt battery. The inverter consumes 2.16 watts, and is 90% efficient. The total consumption from the battery was 42 watts (12V at 3.5 A); once the 2.16 watts is deducted and the efficiency taken into account, we obtain the same 36 W (vibrator stage at max, i.e. 47 clicks, in this experiment). The T/R gap is adjusted to 3", and 2 square ft plates are employed. Transmitter and receiver coils are tuned, and so are the plate capacitances, to 250 kHz, also the capacitances of the Function Y circuit connected at the output of the receiving coil. The rectified voltage and current generated by the transmitter secondary and by the transmitter plate was ascertained with a coil-tuned wave-divider (Function Y) circuit by loading it with different resistive values. The results constitute a measure of the massbound electrical power output directly from the transmitter apparatus. The same method was employed to ascertain the voltage, current and power of the massbound charges circulating in the receiving plate and coil circuit. The results are shown in Table 8 below:

TABLE 8

Massbound currents rectified by Function Y at the output of the Tesla transmitter, transmitter plate and receiver plate, as a function of the bleeding resistance employed in each of the function Y arms

	VDC (kilovolts)	ADC (amp)	WDC (watts)	R/arm (Mohm)
Direct from 20°	42–50	$3*10^{-5}$	1.26–1.5	500
From 2° (T) plate	26	$2*10^{-5}$	0.52	500
From 2° (R) plate	15.1	$1.25*10^{-5}$	0.189	500
Direct from 2°	20.4	$3.4*10^{-4}$	6.936	50
From 2° (T) plate	15.2	$2.4*10^{-4}$	3.648	50
From 2° (R) plate	9	$1.2*10^{-4}$	1.08	50
Direct from 2°	3.3	$1.75*10^{-3}$	5.775	1
From 2° (T) plate	3.5	$2*10^{-3}$	7.0	1
From 2° (R) plate	2.95	$1.6*10^{-3}$	4.72	1

The results indicate that the highest massbound power assembled by the secondary transmitter circuit does not exceed 7 watts—and this is directly output from the secondary **26** when the load is 50 Mohm, or from the transmitter plate when the load is 1 Mohm. The massbound electric power emulated by the receiving circuit (plate, coil and Function Y without the plasma pulser circuitry) never exceeds the massbound electric power output directly by the transmitter, and peaks when the resistive load value (1 Mohm) approaches the pre-breakdown resistance range of the vacuum tube, at 4.72 W. These findings then indicate that when the transmitter circuit is consuming a maximum of 35 W, a typical output from the secondary of the transmitter is 7 W, and at 3" of distance within the proximal field of the latter, the pick-up by a tuned receiver will be on the order of 5 W of massbound current duplicated within the receiving coil. The loss in the first stage is therefore on the order of sevenfold. Continuing with the description of the circuit of FIG. **19**, a 128 cm^2 plate area, 6 cm gap PAGD reactor is employed, connected as described in our prior art to a high-vacuum rotary pump (Correa, P & Correa, A (1995) "Energy conversion system", USPTO U.S. Pat. No. 5,449, 989.). Pressure readings were obtained with a thermocouple gauge during the operational runs. The KS-9303 motors to be tested are then connected to the PAGD reactor in the usual capacitatively-coupled, inverter fashion described in our prior art (Correa, P & Correa, A (1995) "Electromechanical transduction of plasma pulses", USPTO U.S. Pat. No. 5,416, 391.). Their rpm is detected by a stroboscopic tachometer and fed to a Mac Performa 6400 running a motor algorithm program calculating the power output. Motor measurements were made at five minutes into each run for the unloaded motors, and at ten minutes for the inertially damped motors. All experiments were carried out in the same work session. The experimental determination of the continuous rotary power output as a function of the reactor pulse rate confirmed that the improved circuit develops maximum rotary capture of the massfree energy in the receiver circuit at the lowest rates of pulsation, just as we have previously found for the conversion system of U.S. Pat. No. 5,449,989. Furthermore, the data showed that even motors of type KS-8624 are able to output power mechanically in excess of the massbound power output by the transmitter (7 W) or captured by the receiver (5 to a max of 7 W), once the PAGD rate decreases to 1.5 PPS. Such an anomaly can only be explained by the system having become able to begin capturing the massfree energy flux in the receiver circuit that we know already is output by the transmitter circuit. But this excess mechanical power is still, and clearly so, less than the power input into the transmitter. It represents a power gain with respect to the secondary, but a loss with respect to the primary. The full breadth of the capture of the massfree electric energy flux circulating in the receiver circuit is not seen until the motors are resonantly loaded because they are inertially damped.

The KS-9303 motors, once inertially damped, and thus loaded, are able to to recover enough power from the massfree energy field to develop a mechanical power, not just greatly in excess of the massbound power of the secondary, but also greatly in excess of the massbound power input to the vibrator stage and the primary, at 28 to 35 W. Once the pulse rate approaches the same 1.5 PPS marker, mechanical power in excess of the massbound electric power input to the primary becomes evident, peaking at nearly three times that input. In fact, the highest output recorded was also obtained with the lowest input to the transmitter circuit, the highest exact coefficient observed in this experiment being 100.8 W/28 W=3.6. Furthermore, with respect to the secondary massbound output, the same mechanical rotary output represents a much greater overunity coefficient of performance, on the order of 14.4 times greater. This is at least partly the result of the receiver and motor capture of the massfree electric energy output by the transmitter, and may be partly the result of massfree energy engrafted by the PAGD regime in the PAGD reactor. Reviewing the mechanical power output results as a function of increasing vacuum in the PAGD reactor and at different output power levels, any motor performance below the 5–7 W limit of the traditional massbound output power of the secondary represents an output mechanical power loss with respect to both the massbound secondary output and the massbound primary input. All the results for pressures down to 0.03 Torr fall in this category, and thus represent a very inefficient coupling to the PAGD regime. Any motor performance between 7 W and 28–35 W represent a loss with respect to the electrical power input to the transmitter system, but a net gain of power with respect to the massbound secondary power output. None of the non-inertially damped motors tested were able to perform outside of this area, under the test conditions. With more efficient primary to secondary couplings in the transmitter station, however, one could advantageously employ these motors alone to extract some of the massfree power of the secondary or to operate them in enclosed vessels without conventional external electrical connections. To reach satisfactory levels of recovery of massfree energy, one must dampen the superimposed DW impulses. Hence, all results showing outputs in excess of 35 W were obtained using the inertially damped KS-9303 motors, and represent a net overunity power gain over both the power input to the primary and the massbound power output by the secondary, or the massbound power emulated by the receiver circuitry. This happens when the PAGD pulse rate falls to 2 PPS, with the rotary power output steeply increasing as the rate falls to 1 PPS.

One of the interesting features of the motor circuitry we have proposed is that it can operate with pulsed plasmas in both the TRD and the AGD regions, the least efficient response occurring in the NGD region near the Paschen minimum. One might think that the voltage depression would allow increased current intensity supplied to the motors, but in fact that is not observed, with the flashing of the NGD yielding erratic oscillations and low values of current. In keeping with the notion that the TRD plasma is mainly composed of lagging positive ions, whereas the PAGD plasma is mostly an electron plasma, the observed direction of rotation of the motors is opposite in the TRD region to that of the AGD region. The NGD region therefore marks the depression where the velocity vectors change direction. In the second or PAGD region, motor operation is very quiet, unlike what is observed in the TRD region.

Part and parcel of the tuning of the circuit components is the selection of the optimum capacitances employed to couple the PAGD reactor to the motor circuit and split the phase to feed the auxiliary winding of the motor. We have experimented with capacitances ranging from 0.5 to 100 μF, and found that best results—for the specific circuit in question (including the characteristics of the transmission)—were such that the optimal value of the PAGD coupling capacitance lay near 4 pF, and the phase splitting capacitance, near 1 to 4 μF, depending upon weather conditions—in good weather days lower capacitance values can be implemented, and in bad weather days higher capacitances are needed. For ease of comparison in demonstrating the need to tune the circuit by employing optimal capacitances in those two couplings (reactor to motor, and motor phase coupling), we employed the same capacitances in both circuit locations. A comparison of tests using 1 and 4 μF values shows the difference caused by changing those capacitances from their optimal value: across all discharge regions of the pressure range that was examined, the four motors tested operating with greater motor speeds when the capacitances are set to 4 μF rather than to 1 μF. The less efficient performance obtained with 1 μF capacitances fits the inverse correlation of pulse power with increasing pulse frequency, such as we have found for the PAGD regime. This is made evident by a comparison of rpm versus pulse rate for the two capacitance values being considered. They demonstrate the higher pulse rates observed with the lower capacitance, that correlate with the slower motor speeds, and result in lower efficiency of the motor response. The results equally indicate that low capacitance values increase the pulse rate, but if this increase is out of tune with the rest of the circuit values, it results in power waste because it imposes a rate that is not optimal.

We have also experimentally determined that the efficiency of the system is affected by external weather conditions, higher efficiencies being noted on a fine bright day than under poor weather conditions even though the apparatus is not exposed to such conditions. This may reflect a diminution under poor weather conditions of latent massfree energy that can be taken up by the system.

The observed high efficiency of circuits including inertially damped motors indicates that the phenomenon does not reduce to a mere optimal capture of DC-like pulses produced by the reactor in what is essentially an AC motor circuit. Effectively, the pulsed plasma discharge deploys a front-end, DC-like pulse, or discontinuity, but this is followed by an AC-like damped wave of a characteristic frequency (having a half-cycle periodicity identical to that of the front-end pulse) to which the motor circuit also responds. Moreover, the massfree electric radiation from the transmitter circuit itself induces—in the receiver antenna, coil and circuit, and in the reactor discharge itself—the train of finer damped wave impulses responsible, after conversion through the wave-divider, for the massbound rectified current that is employed to charge the plasma reactor to begin with. Serving as trigger of the plasma discharges in the reactor are the DW impulses circulating in the receiver circuit, such that the two different lines of DW impulses, in the receiver circuit (for example 120 PPS for the pulses and 154 kHz for the waves) and from the reactor, are synchronized by interpolated coincidences, since their pulse and wave frequencies are different. Ideally, these two superimposed DW frequencies are harmonics or made identical. The receiver stage involves capture of the massfree electric energy received from the transmitter, duplication of the massbound current in the receiver coil, and injection of latent and sensible thermal energy in the T/R gap cavity that augments the emulated massbound current. The massbound current is employed to charge the wave-divider capacitance bridge and therefore the reactor. In turn, the plasma pulses from the reactor are superimposed with the DW impulses from the receiving coil, and together they are coupled to the split-phase motor drive. Hence the first receiver stage employs the totality of the energy captured in the T/R gap cavity-massfree electric energy transmitted by the T plate, latent and sensible thermal energy injected at the surface of the R plate—and produces in the receiving coil a massbound current comparable to that assembled in the transmitter coil by the action of the primary. The massbound current is stored in the wave-divider bridge and used to drive the plasma reactor in the PAGD region. Subsequently, the autogenous disruptive discharge that employs a substantial electron plasma generates both a concentrated, intense flux of massbound charges in the output circuit, and a massfree oscillation of its own. The damped motor is therefore fed directly with (1) the intense massbound current output from the reactor; (2) the pulse and wave components of the massfree electric energy captured by the receiver plate and coil (and matched by conduction through the earth), and which are gated through the wave-divider and the reactor for the duration of the PAGD channel; and (3) any massfree latent energy taken up from the vacuum by the PAGD event. Once the motor is set into motion, and is resonantly loaded with an inertial damper, we believe that it will also respond to the much weaker DW impulses captured by the receiver, since these impulses encompass both a DC-like front end—further enhanced by analytic separation through the wave-divider—and a damped wave at 154 kHz. Essentially the DW impulses that are ultimately sourced in the transmitter -and received unipolarly through the T/R gap—have sufficient DC-like potential (plus all the other requisite physical characteristics, such as frequency) to contribute directly to the motor response, once the motor has gained substantial speed (for they lack the current to set it into motion, one of the contributions from the plasma pulser). This is the case, provided that the motor itself is suited for absorption of both DC-like pulses and AC-like damped waves, which is precisely the case with motors of the type shown in FIG. **18** since the inertia of the flywheel is overcome through homopolar absorption of the damped oscillations simultaneously in the motor drag-cup rotor and in the generator drag-cup rotor.

We also tested these inertially damped motors in the traditional DC power supply-driven PAGD circuit we have taught in our previous patents, that is, circuits with an overt HV DC power source, and thus in the absence of any Function Y circuit or transmitter circuit. Here then, only the DW impulses generated by the PAGD reactor can account for the motor response. The tube employed (A31) had an area of 256 cm^2, and a gap distance of 4 cm. Coupling capacitances employed were 4 μF for the inverter coupling, and 1 μF for the split phase motor coupling. The DC power supply delivered up to 1 ampere of current between 150 and 1,000 VDC, and the ballast resistor was adjusted to 215 ohms. Having determined the basic physical characteristics of the reactor's behaviour in the circuit under consideration, we conducted our experiment in the PAGD region. We chose a pressure of 0.6 Torr, just off from the Paschen minimum, as we intended to benefit from the lower sustaining voltage that it affords. The experiment basically consisted of increasing the sustaining voltage at this fixed pressure in the PAGD regime, and measuring the diverse physical parameters of the circuit and motor response in order to ultimately ascertain the difference between the input electric DC power and the output mechanical rotary power. We first looked at how the motor rpm response varied as a function of the sustaining voltage (V_s): the results illustrate the importance of starting close to the Paschen minimum in the pressure scale, since the KS-9303 motors reach plateau response (at 17,000 rpm) when the reactor output voltage nears 450V. Any further increase in potential is simply wasted. Likewise, the same happened when we measured motor speed as a function of increasing peak DC current, plateau response being reached at 0.1 ADC. Again, any further increase in current is wasted. Essentially then, the optimal power input to the reactor when the latter's output is coupled to the motor, lies around 45 watts. This is a typical expenditure in driving a PAGD reactor. As for pulse rate we once again find a motor response that is frequency proportional in the low frequency range, between 10 and 40 PPS (all pulse rates now refer solely to PAGDs per sec), but once rates of >40 PPS are reached, the response of the motor also reaches a plateau. The observed increment in speed from 40 to 60 PPS translates only into an increase of 1,000 RPM, from 16,000 to 17,000 RPM. So, we can place the optimal PAGD rate at ca 40 PPS. The DC electric power input to drive the PAGD reactor was next compared to the rotary mechanical power output by the inertially loaded motor, driven in turn by the reactor. This comparison was first carried out with respect to the PAGD rates. The motor response far exceeds the conventional input power, indicating that the whole system can be tuned to resonance such that optimal power capture inside the reactor takes place, the critical limit rate lying at around 60 PPS, when the motor response is firmly within the pulse response plateau. At this juncture, the break-even efficiency for the measured rates of energy flux over time reach 700% (overunity coefficient of 7), in keeping with the observations and the values we have made in the PAGD conversion system. In the proportional part of the curve, before the plateau is reached, even greater rates of break-even efficiency—up to >1,000% were registered. These results constitute the first time we have been able to confirm the presence of output energy in excess of break-even over conventional mass-bound energy input in the PAGD inverter system, and the results are comparable to what we have observed and previously reported for the PAGD converter system. At pulse rates greater than 60 PPS a greater input power results in decreased efficiency, also translated into a noticeable heating of the reactor and motor. And this is all the more remarkable as experiments we have conducted with inductive tuning of PAGD reactors, or employing PAGD reactors as replacements for the primaries of Tesla coil assemblies, and still, more recently, with the PAGD inverter circuit driving motors, have all shown that it is possible to operate these reactors with minimal mirroring and heating, preserving essentially the cold-cathode conditions and yet focusing the plasma column so that deposition on the insulator is negligible. It appears that above a certain threshold of optimal efficiency, surplus input energy is just dissipated thermally by both the reactor and the motors.

It should be understood that the above described embodiments are merely exemplary of our invention, and are, with the exception of the embodiments of FIGS. **16**–**19** designed primarily to verify aspects of the basis of the invention. It should also be understood that in each of these embodiments, the transmitter portion may be omitted if an external or natural source of Tesla waves is available, provided that the receiver is tuned to the massfree radiation mode of the source. For example if solar radiation is available in which the massfree component has not interacted with the earth's atmosphere (as in space applications), the receiver is tuned to the voltage wave of the massfree radiation sourced in the sun, e.g. by using a Tesla coil in the receiver constructed to have an appropriate voltage wave close to the 51.1 kV characteristic of such radiation.

We claim:

1. A device for the conversion of massfree radiation into electrical or electrokinetic energy comprising a transmitter of massfree electrical radiation having a damped wave component, a receiver of such radiation tuned to resonance with the damped wave frequency of the transmitter, a co-resonant output circuit coupled into and extracting electrical or electrokinetic energy from the receiver, and at least one of a transmission cavity between the transmitter and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed glow discharge device incorporated in the co-resonant output circuit.

2. A device according to claim **1**, wherein the output circuit comprises a full wave rectifier presenting a capacitance to the receiver.

3. A device according to claim **2**, wherein the output circuit comprises an electric motor presenting inductance to the receiver.

4. A device according to claim **3**, wherein the motor is a split phase motor.

5. A device according to claim **4**, wherein the motor is a drag motor having a non-magnetic conductive rotor.

6. A device according to claim **5**, wherein the motor has inertial damping.

7. A device according to claim **6**, wherein the motor has a shaft, a drag cup rotor on the shaft, and inertial damping is provided by a further drag cup on the shaft.

8. A device according to claim **6**, wherein the transmitter and receiver each comprise at least one of a Tesla coil and an autogenous pulsed abnormal glow discharge device.

9. A device according to claim **8**, wherein the transmitter and receiver both comprise Tesla coils, and further including a transmission cavity which comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively.

10. A device according to claim **9**, wherein the plates are parallel.

11. A device according to claim **9**, wherein the plates are concentric.

12. A device according to claim **9**, wherein at least the receiver comprises a Tesla coil driving a plasma reactor operating In PAGD (pulsed abnormal glow discharge) mode.

13. A device according to claim **12**, wherein the transmitter and receiver both comprise Tesla coils, and further Including a transmission cavity which comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively.

14. A device according to claim **1**, wherein the transmitter and receiver each comprise at least one of a Tesla coil and an autogenous pulsed abnormal glow discharge device.

15. A device according to claim **1** wherein a transmitter/receiver cavity is present and filled with an aqueous liquid.

16. A device for the conversion of massfree radiation into electrical or electrokinetic energy comprising a receiver of such radiation from a source of massfree electrical radiation having a damped wave component, the receiver being tuned to resonance with the damped wave frequency of the source, a co-resonant output circuit coupled into and extracting electrical or electrokinetic energy from the receiver, and at least one of a transmission cavity between the source and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed glow discharge device incorporated in the co-resonant output circuit.

(57) **ABSTRACT**

In accordance with the present invention, an aperture rectenna is provided where the substrate is transparent and of sufficient mechanical strength to support the fabricated structure above it. An aperture antenna is deposited on the transparent substrate and a metal-insulator-metal (MIM) diode is constructed on top of the aperture antenna. There is an insulating layer between the aperture antenna metal and the metal ground plane optimized to maximize the collection of incident radiation. The top of the structure is capped with a metal ground plane layer, which also serves as the DC connection points for each rectenna element.

RECTIFYING ANTENNA AND METHOD OF MANUFACTURE

CROSS REFERENCE TO RELATED APPLICATION

This application claims priority to Provisional U.S. Patent Application No. 60/514,327, "An Aperture Rectenna for Converting High Frequency Radiation into DC Power", by the same inventors, filed Oct. 24, 2003.

STATEMENT OF GOVERNMENT INTEREST

Research relating to the present application was supported by NASA/FSEC. Accordingly, the U.S. federal government may have rights in the present invention.

BACKGROUND OF THE INVENTION

Light energy is characterized by a dual nature both from a quantum point of view as photons and from a wave point of view as randomly polarized electromagnetic radiation with wavelengths from 400 nm to 700 nm. If the ultraviolet and infrared portion of the spectrum is included, the range of wavelengths is extended at both extremes. Presently all practical solar cell energy collection schemes use the photon nature of light in the explanation of operation. The conversion of solar energy to electrical energy using the photovoltaic effect depends on the interaction of photons with energy equal to or greater than the band-gap of the material. With continued research the maximum amount of energy captured using this mechanism is estimated to be around 30%. This is equivalent to an efficiency of 30%.

Another mechanism known in the art for converting solar energy to electrical energy is the rectenna. Rectenna technology relies on the electromagnetic nature of radiation and is not limited by the band-gap of the rectifying material. Advantages exist in the rectenna field because the rectenna approach is not fundamentally band-gap limited. Also, at microwave frequencies, 2.45 GHz, this concept has been demonstrated to be approximately 90% efficient.

Prior art exists in the field of rectenna technology. The idea of direct electromagnetic conversion of solar energy has been explored as early as 1973. The concept envisioned small cone type antennas with rectifiers mounted behind the cones and the cones arranged in an array as illustrated in FIG. **1**. The work preceded the revolution in micro and nano scale manufacturing and was never realized. Other more recent researchers have replaced the cones with planar antenna elements such as half-wave dipoles, bow tie, and spiral antennas.

The previous efforts in researching rectennas for solar energy conversion have concentrated on either building the rectifiers on a supporting substrate and then building the antennas on top of the rectifying layer, or fabricating the antenna structure and the rectifier on a planar surface. The fabrication processes known in the art for rectenna elements rely on hybrid systems that incorporate different technologies for each component of the rectenna to optimize the system performance. While the incorporation of hybrid technologies often allows for a shorter development time, compromises must be made to ensure that each component can be fabricated without damaging components already existing on the substrate.

By contrast, monolithic device fabrication allows for all components of a system to be constructed on a single substrate utilizing one technology. Monolithic devices are typically more compact than hybrid devices, and more reliable due to the reduction in interconnections required. Additionally, once the fabrication process for a monolithic device has been developed, they can be manufactured more efficiently since less assembly is required. Monolithic technology minimizes relatively long, high-resistivity connections and high loss metal interconnects.

Accordingly, what is needed in the art is a monolithic rectifying antenna providing high efficiency solar energy conversion with improved reliability and manufacturability.

However, in view of the prior art considered as a whole at the time the present invention was made, it was not obvious to those of ordinary skill in the pertinent art how the identified need could be fulfilled.

SUMMARY OF THE INVENTION

The longstanding but heretofore unfulfilled need for a monolithic rectifying antenna providing high efficiency solar energy conversion with improved reliability and manufacturability superior to rectifying antennas known in the art is now met by a new, useful, and nonobvious invention.

The present invention provides an integrated approach, at the nano-scale level, to fabricate a slot or aperture antenna integrated with a metal-insulator-metal (MIM) quantum tunneling diode to form a building block element in an array of rectenna elements for harvesting electromagnetic energy such as that emanating from the sun.

While many variations on the theme of an antenna coupled with a high frequency rectifier to harvest electromagnetic energy are known in the art, the present invention provides a novel and nonobvious solution to problems associated with prior art devices. In accordance with the present invention, an integrated nano-scale aperture antenna with a rectifier integrated using nano-scale monolithic processing is provided. Additionally, the rectifying antenna in accordance with the present invention lends itself to an inverted structure with the antenna deposited first on a transparent substrate and the rectifier and DC collection metallization fabricated on top of the antenna portion.

In accordance with the present invention is provided a rectifying antenna, comprising a transparent substrate layer, an aperture antenna fabricated on a surface of the transparent substrate, a rectifier having an anode and a cathode, the anode and the cathode electrically connected to the aperture antenna and separated from each other, the rectifier fabricated on top of the aperture antenna, a dielectric layer deposited to cover the aperture antenna and the rectifier, and a metal ground plane deposited over the dielectric layer, the metal ground plane being in electrical connectivity with the anode and the cathode of the rectifier.

While many materials may be used for the transparent substrate, in a particular embodiment the transparent substrate layer is glass.

The aperture antenna is fabricated is fabricated on the transparent substrate by depositing metal onto the surface of the transparent substrate and etching away the metal to form a slot and a dc break in the metal layer to reveal the transparent substrate, the slot and the dc break being contiguous. In a particular embodiment, the metal is gold, however other metals or metal alloys are within the scope of the present invention.

In a particular embodiment, the rectifying antenna includes an aperture or slot etched in the metal layer that is approximately $3\lambda/4$ in major length and approximately $\lambda/10$ in width, where λ is the center wavelength of the radiation to be collected. The radiation to be collected may be emanating from the sun or another source of electromagnetic radiation as is known in the art.

The rectifying antenna in accordance with the present invention additionally includes, a dc break etched in the metal layer. In a particular embodiment, the dc break is etched to establish a slot through to the transparent substrate that is approximately λ/4 in major length.

To accommodate the positioning of the rectifier relative to the aperture antenna, the slot fabricated for the antenna further comprises a metal rectifier pad located approximately in the center of the slot and having a width of less than λ/10. This metal rectifier pad may be referred to as a conducting indentation and connectivity to one side of the rectifier as in the case of a metal-insulator-metal rectifier.

In a particular embodiment, the dielectric layer deposited to cover the antenna and the rectifier is fabricated to maximize the collection of radiation incident on the aperture antenna. In a particular embodiment, the dielectric layer is approximately λ/4 in thickness. In an additional embodiment, the dielectric layer is selected from the group consisting of ceramic, mica, glass, plastic and metal oxides.

While various rectifier elements are within the scope of the present invention, in accordance with a particular embodiment, the rectifier is a metal-insulator-metal (MIM) rectifier. As such, a first metal having a first potential and a second metal having a second potential are utilized in the fabrication of the MIM rectifier. In a particular embodiment, the first metal is platinum, the second metal is palladium, and the insulator of the MIM rectifier is selected from the group consisting of silicon dioxide, silicon nitride and aluminum oxide.

In accordance with an additional embodiment, the MIM rectifier may be replaced by a bolometer.

In an additional embodiment, a matching transmission line may be fabricated between the antenna and the rectifier to provide impedance matching. Additionally, a cooling mechanism may be employed in accordance with the present invention. The implementation of the cooling mechanism including, but not limited, to a liquid cooling channel positioned coincident with the ground plane or a silicon passive heat exchanger module.

To reduce the harmonics inherent in the rectifying antenna, it is within the scope of the invention to provide at least one notch filter positioned between the antenna and the rectifier in an effort to reduce unwanted harmonics.

In providing a rectifying antenna in accordance with the present invention, a method may be employed including the steps of, providing a transparent substrate layer, fabricating an aperture antenna on a surface of the transparent substrate, fabricating a rectifier on the surface of the aperture antenna, the rectifier having an anode and a cathode, the anode and the cathode electrically connected to the aperture antenna and separated from each other, depositing a dielectric layer to cover the aperture antenna and the rectifier and depositing a metal ground plane over the dielectric layer, the metal ground plane being in electrical connectivity with the anode and the cathode of the rectifier.

While various method are known in the art for the fabrication of elements on substrate materials, in a particular embodiment of the present invention the step of fabricating an aperture antenna on a surface of the transparent substrate further includes, depositing a first metal on the surface of the transparent substrate layer, etching away the deposited first metal to form a slot for the aperture antenna and a dc break.

In a particular embodiment, the rectifier element is a metal-insulator-metal rectifier. The method of fabricating the MIM rectifier further includes, forming a conducting indentation in the center of the antenna slot, the conducting indentation fabricated of a first metal and establishing the anode of the rectifier, depositing a dielectric layer on top of the conducting indentation and fabricating a second metal layer on top of the dielectric layer to form the metal-insulator-metal rectifier across the aperture antenna. In a preferred embodiment, the dielectric layer of the MIM rectifier is between approximately 1.5 nm and 2 nm and the second metal layer is deposited to a thickness of approximately 50 nm. These dimensions are intended to be exemplary and other thicknesses of the dielectric and the second metal layer are considered within the scope of the invention.

In an additional embodiment, a dielectric layer to cover the aperture antenna and the rectifier further is deposited and planarized to form a dielectric layer of substantially uniform thickness of λ/4, while other thicknesses are within the scope of the invention.

In accordance with the present invention, a plurality of rectifying antennas formed in accordance with the method as described may be connected to form an array of rectifying antennas.

As such, the present invention provides a monolithic rectifying antenna exhibiting high efficiency solar energy conversion with improved reliability and manufacturability.

With the present invention, the dc current travels in the z-direction thereby eliminating many lossy electrical connections due to additional metal interconnects, thereby improving reliability. The manufacturing of the device requires a minimal investment in nanotechnology manufacturing techniques.

Additionally, the delicate structures of the device are protected by the glass substrate.

Other aspects and advantages of the present invention can be seen upon review of the figures, the detailed description, and the claims, which follow.

BRIEF DESCRIPTION OF THE DRAWINGS

For a fuller understanding of the nature and objects of the invention, reference should be made to the following detailed description, taken in connection with the accompanying drawings, in which:

FIG. **1** is a prior art illustration of small cone type antennas with rectifiers mounted behind the cones and the cones arranged in an array;

FIG. **2** is an illustration of a first metal layer on top of a substrate in accordance with the present invention;

FIG. **3** is an illustration of a dielectric layer with windows to a first metal (metal #1) in accordance with the present invention;

FIG. **4** is an illustration of a structure with a second metal (metal #2) in place and DC vias in accordance with the present invention;

FIG. **5** is an illustration of a top metal ground plane and DC connections in accordance with the present invention; and

FIG. **6** is an illustrated cross sectional edge view of a rectifying antenna, or rectenna, in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The method in accordance with the present invention establishes a fabrication process to provide a smooth, strong surface to build an aperture antenna on and thus allow the construction of the rectifier on top of the antenna to minimize relatively long, high-resistivity and high loss metal interconnects. In a particular embodiment, a 3λ/4 slot antenna concept described by the present invention has been exemplified. Additional slot antenna dimensions are within the scope of the present invention.

The method in accordance with the present invention allows for the easy adaptation of dissimilar two metal metal-insulator-metal (MIM) rectifiers. In a particular embodiment, the MIM is build utilizing two metals exhibiting large differences in potential such as Pt or Pd combined with Au or W or Al. The structure requires a dielectric substance, such as SiO_2, Silicon Nitride or Aluminum Oxide. Other insulating materials are within the scope of the present invention.

With reference to FIG. **2**, a rectifying antenna and method of manufacturing the same is provided wherein the construction of a slot rectenna includes the steps of, selecting a suitable transparent substrate **10**, like glass, on which to build the structure, depositing a metal **15**, like gold, and then etching away the slot **25** and dc break **20** as illustrated. The imaginary centerline **30** is also illustrated.

In a particular embodiment, the slot etched in the first metal (metal #1) layer opens a hole down to the transparent substrate, which is approximately 3λ/4 in major length and approximately λ/10 in width. Where λ is the center wavelength of the radiation to be collected and corrected for dilation due to the permitivity of the substrate. With reference to FIG. **2**, the conducting indentation **35** in the center of the slot, will become one side of the MIM rectifier and the thin λ/4 slot extension on the right **20**, will become the ac capacitive short/dc break for the structure. The ac capacitive short acts as a filter to separate the ac and dc components of the received signal.

After the slot **25** is etched in the metal layer, a dielectric layer **40** λ/4 thick is deposited over the entire first metal layer **15**. Holes are opened in the dielectric layer to facilitate the second metal (metal #2) deposition. This is illustrated in FIG. **3** where the dielectric layer **40** has been deposited and holes **45**, **50**, **55** and **60** have been opened up to the metal #1 layer below.

In the process of opening the dielectric layer **40** certain areas such as the little pad **45** where the rectifier is to be constructed and one side of the ac capacitive short **60** must still have a thin layer of insulation **40**. For the rectifier pad **45** this layer should be between 1.5 nm and 2 nm and for the capacitive short **60** the insulation should be thicker than 10 nm.

At this point in the fabrication process, the second metal layer **65** is deposited. The second metal layer **65** is approximately 50 nm thick. After the second metal layer **65** is deposited it is etched away from areas where it is not wanted, as shown in FIG. **4**. As such, the metal-insulator-metal rectifier **75** is formed. Above metal #2 (second metal) the insulation layer is replaced and planarized **90** so it is a uniform layer of thickness λ/4 then the window for the two dc vias, **80** and **85**, are opened up.

A final layer of the same material as metal #1 is then deposited to form a ground plane **95** and provide connection points to the +via **85** and −via **80** as illustrated in FIG. **5**.

If the rectifying antennas were incorporated into an array, the top layer of the system would include interconnection of the individual rectenna elements so energy could be effectively captured on a macroscopic scale.

With reference to FIG. **6**, an edge sectional view taken through the centerline **30** of the slot is shown.

In accordance with the present invention, the MIM can be constructed of a large variety of conducting metal combinations, the insulation can be inorganic as has been described or organic and can be made of many different types of materials. The shape of the slot and the diode may be varied. Due to impedance matching concerns between the antenna and the rectifier the dimensions of the slot may vary and it may be necessary to incorporate a matching transmission line between the antenna and the rectifier. Optional cooling methods may be employed such as liquid cooling channels next to the metal layer or a silicon passive heat exchanger module.

The non-linear nature of the rectifier causes the generation of harmonics. To prevent the loss of efficiency associated with the re-radiation at higher harmonics it is within the scope of the present invention to incorporate notch filters between the antenna and the rectifier.

Additionally, the array of slot rectennas could be replaced with an array of monopole traveling wave antennas manufactured using carbon nano-tube technology. The nano-tube antennas would be several wavelengths long and have a MIM built into their base.

In another embodiment of the invention, replaces the slot antenna with either a slot parasitic array antenna or a dipole parasitic array antenna. The use of the array concept maintains the high collection density, and handles the polarization problem to reduce the number of MIM structures required for energy conversion.

It will be seen that the objects set forth above, and those made apparent from the foregoing description, are efficiently attained and since certain changes may be made in the above construction without departing from the scope of the invention, it is intended that all matters contained in the foregoing description or shown in the accompanying drawings shall be interpreted as illustrative and not in a limiting sense.

It is also to be understood that the following claims are intended to cover all of the generic and specific features of the invention herein described, and all statements of the scope of the invention which, as a matter of language, might be said to fall therebetween. Now that the invention has been described,

What is claimed is:

1. A rectifying antenna, comprising:

a transparent substrate layer;

an aperture antenna fabricated on a surface of the transparent substrate;

a rectifier having an anode and a cathode, the anode and the cathode electrically connected to the aperture antenna and separated from each other, the rectifier fabricated on top of the aperture antenna;

a dielectric layer deposited to cover the aperture antenna and the rectifier; and

a metal ground plane deposited over the dielectric layer, the metal ground plane being in electrical connectivity with the anode and the cathode of the rectifier.

2. The rectifying antenna of claim **1**, wherein the transparent substrate layer is glass.

3. The rectifying antenna of claim **1**, wherein the aperture antenna is fabricated of a metal.

4. The rectifying antenna of claim **3**, wherein the metal is gold.

5. The rectifying antenna of claim **1**, wherein the aperture antenna is fabricated by depositing metal onto the surface of the transparent substrate and etching away the metal to form a slot and a dc break in the metal layer to reveal the transparent substrate, the slot and the dc break being contiguous.

6. The rectifying antenna of claim **1**, wherein the slot etched in the metal layer is approximately 3λ/4 in major length and approximately λ/10 in width, where λ is the center wavelength of the radiation to be collected.

7. The rectifying antenna of claim **5**, wherein the dc break etched in the metal layer is approximately λ/4 in major length.

8. The rectifying antenna of claim **5**, wherein the slot further comprises a metal rectifier pad located approximately in the center of the slot and having a width of less than λ/10.

9. The rectifying antenna of claim **1**, wherein the dielectric layer is fabricated to maximize the collection of radiation incident on the aperture antenna.

10. The rectifying antenna of claim **1**, wherein the dielectric layer is approximately λ/4 in thickness.

11. The rectifying antenna of claim **1**, wherein the dielectric layer is selected from the group consisting of ceramic, mica, glass, plastic and metal oxides.

12. The rectifying antenna of claim **1**, wherein the rectifier is a metal-insulator-metal rectifier.

13. The rectifying antenna of claim **12**, wherein the metal-insulator-metal rectifier is fabricated using a first metal having a first potential and a second metal having a second potential.

14. The rectifying antenna of claim **13**, wherein the first metal is platinum.

15. The rectifying antenna of claim **13**, wherein the second metal is palladium.

16. The rectifying antenna of claim **12**, wherein the insulator of the metal-insulator-metal rectifier is selected from the group consisting of silicon dioxide, silicon nitride and aluminum oxide.

17. The rectifying antenna of claim **1**, wherein the rectifier is a bolometer.

18. The rectifying antenna of claim **1**, further comprising a matching transmission line fabricated between the antenna and the rectifier to provide impedance matching.

19. The rectifying antenna of claim **1**, further comprising a cooling mechanism.

20. The rectifying antenna of claim **19**, wherein the cooling mechanism is a liquid cooling channel positioned coincident with the ground plane.

21. The rectifying antenna of claim **19**, wherein the cooling mechanism is a silicon passive heat exchanger module.

22. The rectifying antenna of claim **1**, further comprising at least one notch filter positioned between the antenna and the rectifier to reduce harmonics.

23. A method of fabricating a rectifying antenna, the method comprising the steps of:

providing a transparent substrate layer;

fabricating an aperture antenna on a surface of the transparent substrate;

fabricating a rectifier on the surface of the aperture antenna, the rectifier having an anode and a cathode, the anode and the cathode electrically connected to the aperture antenna and separated from each other;

depositing a dielectric layer to cover the aperture antenna and the rectifier; and

depositing a metal ground plane over the dielectric layer, the metal ground plane being in electrical connectivity with the anode and the cathode of the rectifier.

24. The method of claim **1**, wherein the step of fabricating an aperture antenna on a surface of the transparent substrate further comprises:

depositing a first metal on the surface of the transparent substrate layer; and

etching away the deposited first metal to form a slot for the aperture antenna and a dc break.

25. The method of claim **24**, wherein the step of etching the deposited first metal further comprises:

etching away the deposited first metal to form a slot approximately 3λ/4 in major length and approximately λ/10 in width, where λ is the center wavelength of the radiation to be collected; and

etching away the deposited first metal to form a dc break approximately λ/4 in major length.

26. The method of claim **23**, wherein the step of fabricating a rectifier on the surface of the aperture antenna, the rectifier having an anode and a cathode, the anode and the cathode electrically connected to the aperture antenna and separated from each other, further comprises, fabricating a metal-insulator-metal rectifier.

27. The method of claim **26**, wherein the step of fabricating a metal-insulator-metal rectifier further comprises:

forming a conducting indentation in the center of the antenna slot, the conducting indentation fabricated of a first metal thereby forming the anode of the rectifier;

depositing a dielectric layer on top of the conducting indentation;

fabricating a second metal layer on top of the dielectric layer to form the cathode of the rectifier, thus forming a metal-insulator-metal rectifier across the aperture antenna.

28. The method of claim **27**, wherein the step of depositing a dielectric layer on top of the conducting indentation further comprises, depositing a dielectric layer between approximately 1.5 nm and 2 nm in thickness.

29. The method of claim **27**, wherein the step of fabricating a second metal layer further comprises fabricating a second metal layer approximately 50 nm in thickness.

30. The method of claim **23**, wherein the step of depositing a dielectric layer to cover the aperture antenna and the rectifier further comprises, depositing a dielectric layer approximately λ/4 in thickness.

31. The method of claim **23**, wherein the step of depositing a dielectric layer to cover the aperture antenna and the rectifier further comprise planarizing the dielectric layer to form a dielectric layer of substantially uniform thickness of λ/4.

32. The method of claim **23**, further comprising connecting a plurality of rectifying antennas to form an array of rectifying antennas.

33. The method of claim **23**, further comprising fabricating a matching transmission line between the antenna and the rectifier to improve impedance matching.

34. The method of claim **23**, further comprising fabricating cooling channels coincident with the first metal layer.

35. The method of claim **23**, further comprising fabricating a silicon passive heat exchanger module coincident with the substrate layer.

36. The method of claim **23**, further comprising fabricating at least one notch filter between the antenna and the rectifier to reduce harmonics.

(57) **ABSTRACT**

A rectenna structure comprising a flexible, dielectric sheet of material; a plurality of metallic lenslets disposed on the sheet of material; and a plurality of diodes disposed on the sheet of material, each diode in said plurality of diodes being arranged at a focus of a corresponding one of said plurality of metallic lenslets.

LARGE APERTURE RECTENNA BASED ON PLANAR LENS STRUCTURES

RELATED APPLICATIONS

This disclosure is related to U.S. Patent Application Ser. No. 60/470,027 entitled "Meta-element Antenna and Array" filed May 12, 2003 and to U.S. Patent Application Ser. No. 60/470,028 entitled "Steerable Leaky Wave Antenna Capable for Both Forward and Backward Radiation" filed May 12, 2003. The disclosures of these applications are hereby incorporated herein by reference. This disclosure is also related to two non-provisional applications that were filed claiming the benefit of the aforementioned applications. The two non-provisional applications have Ser. Nos. 10/792,411 and 10/792,412 and were both filed on Mar. 2, 2004. The disclosures of these two non-provisional applications are also incorporated herein by reference.

TECHNICAL FIELD

The technology disclosed herein relates to a lightweight, high-efficiency rectenna and to a method or architecture for making same. Rectennas can be useful for a variety of applications in the field of beaming RF power, which can be useful for satellites, zeppelins, and UAVs.

BACKGROUND OF THE INVENTION

Rectennas are antenna structures that intentionally incorporate rectifying elements in their designs.

Satellites are an integral part of modern communication systems, and their importance can be expected to grow in the coming years. As future generations of satellites with greater capabilities become possible, it is expected that they can take an even more active role in future military conflicts.

The design of present-day satellites often involves tradeoffs among such aspects as weight, power, and electronic capabilities. Each new electronic system adds weight, and must compete for power with other required systems such as station keeping. The limits of these tradeoffs are eased only gradually from one generation to the next, by the evolution of electronics, batteries, propulsion systems, and so on. Thus, developing new technologies that significantly expand the available design space is crucial to the enablement of satellites with radically improved capabilities over the present generation.

Power supply or generation is one area where revolutionary changes could significantly expand satellite capabilities. Presently, power sources are limited to solar panels or on-board power supplies. Solar panels require continuous exposure to the sun, or the use of batteries to supply power during periods of darkness. Any on-board power system such as a battery adds weight, which reduces the number of electronic systems that can be flown. Furthermore, a system of solar panels and/or on-board sources is best suited to continuous power at moderate levels, and cannot easily supply high-energy bursts without significant additional weight in order to collect and store, and then release the energy.

One way of providing a more flexible power source is to beam the power from a ground station **10** to a satellite **20**, as illustrated in FIG. **1**. This concept has been explored in the past, but in the opposite direction: beaming power to earth (which seemed attractive during the energy crisis). Sending power in the space to earth direction faces certain fundamental limits that make it impractical, but these limits are eased in the earth to space direction, leading to a system that is within the realm of possibility.

In addition to satellites, there are many other applications where beaming power could be important. For example, it is possible to replace hundreds of civilian cellphone base stations with a single zeppelin **20'**, shown in FIG. **2**, which could service a large metropolitan area **25** with mobile telephony, as well as such other services as "satellite" television. This would provide a low-cost alternative to satellites for many commercial wireless applications.

Furthermore, other applications include small UAVs (Unmanned Aerial Vehicles) that could be powered by beamed energy. See FIG. **3**. As the size of a UAV is reduced, the amount of weight that it can carry limits its lifespan significantly. For example, 100-gram airplanes have been built, but their lifetime is limited to six minutes with currently available batteries. By beaming power to a micro-UAV **20"**, it could stay aloft much longer. This would be useful for such applications as law enforcement, surveillance, hazardous site investigation, etc., in addition to the obvious military applications.

The embodiments of FIGS. **1**–**3** assume that the source of power is from a ground station **10**. However, the source of power need not necessarily be terrestrial. The source of power could be airborne or even in space.

Any beamed power system must confront the fundamental limits summarized by the Friis transmission equation, which relates the total power transmitted to the gain, G, of the transmitting and receiving antennas, the distance between them, R, and the wavelength λ of the radiation used.

$$P_{Rx} = G_{Tx} G_{Rx} \left(\frac{\lambda}{4\pi R}\right)^2 P_{Tx} \qquad [1]$$

Assuming for simplicity that both antennas are circular, the gain of each is related to its diameter, D.

$$G = \left(\frac{\pi D}{\lambda}\right)^2 \qquad [2]$$

If one assumes for the moment that very little power will be lost to spillover (this requirement can be relaxed) these equations can be combined to yield an expression for the required sizes of the transmitting and receiving antennas, as a function of their separation, and the wavelength of the radiation used. See FIG. **4**, which depicts the geometry involved in equation 3, to determine the required diameters for the transmitting and receiving antennas.

$$D_{Tx} D_{Rx} = \frac{4}{\pi} R\lambda \qquad [3]$$

For a given separation, reducing the wavelength reduces the size requirements of the transmitter and/or receiver. One tempting solution is to use optical wavelengths, and beam power to space with a large earth-based laser. This has several drawbacks, including scattering by atmospheric turbulence and airborne particles, the typically low wall-plug efficiencies of lasers compared to microwave sources, and the losses in conversion back to DC by photovoltaic cells.

Lasers may be viable alternatives for stationary, near-earth applications such as zeppelins, but not for moving applications, such as micro-UAVs. Their utility for satellites is questionable.

The next candidate wavelength range after optical (skipping terahertz frequencies, which are currently not feasible) is millimeter waves. In the 90–100 GHz range, the attenuation for a one-way trip through the atmosphere can be as little as 1 dB (See Koert, 1992, infra). Furthermore, efficient high-power sources are available, such as the gyrotron, which can produce as much as 200 kW of continuous power at millimeter wave frequencies, at an efficiency of 50% (See Gold, 1997, infra). For higher power applications, arrays of klystrons have been proposed that could produce tens of megawatts of power. These existing high-power sources suggest that it could be possible to temporarily supply a satellite with much higher power from the ground than can currently be produced in orbit. For comparison, the most powerful commercial satellite that is available, the Boeing 702, operates at 25 kW from on-board solar panels. These power sources would be more than adequate for airship applications, and the power required for micro-UAVs would only be on the order of watts.

The most significant engineering challenge for efficient earth to space power transmission is the design of the transmitting and receiving antennas. Fortunately, the receiver design is greatly simplified by the development of the rectenna, (See Brown, 1984, infra) which consists of an array having a rectifier diode at each element. Converting to DC directly at each antenna eliminates the requirement for a perfectly flat phase front, and permits the receiving aperture to take any shape. The transmitter must still produce a coherent beam, so a parabolic dish or other method of phase control is necessary. This is one reason why space to earth transmission is impractical. To illustrate the possibility of high-efficiency earth to space transmission, consider the following example.

Assume that 100 GHz radiation is to be used. The maximum transmitter gain is determined by the ability to accurately build a large dish with the necessary smoothness. The Arecibo dish, which operates at 10 GHz, is 300 meters in diameter. First, assume that a 100 GHz dish could be similarly built with a diameter of 30 meters.

Next, assume that a low-earth-orbit (LEO) satellite is utilized, at an altitude of 500 km. Using equation 3, the required receiver diameter for high transmission efficiency is about 60 meters. This can be compared to the Boeing 702 solar panel wingspan of 47 meters. Thus, structures of the required sizes can be built, both on earth and in space.

However, existing rectenna designs are not practical for space power applications because they require an enormous number of diodes to cover such a large area. For the example just described, one diode per half-wavelength at 100 GHz equates to 6 billion diodes. Using 12-inch wafers, and assuming an area of 1 mm square per diode, this represents the yield of 20,000 wafers; the weight and cost of the diodes alone would be prohibitive.

Another problem with space power applications using traditional rectenna designs is that the power density is too low to achieve significant efficiency. The efficiency, h, of a rectenna is related to the voltage across the diodes, V_D, and the built-in diode voltage, V_{bi} (See McSpadden, 1998, infra).

$$\eta \propto \frac{1}{1 + V_{bi} / V_D} \qquad [4]$$

Designs with efficiencies as high as 90% have been demonstrated, [Strassner, 2002] but the power densities involved were much higher than one could expect to encounter in space. For the LEO example given above, the power density would be 6 mW/cm^2, which corresponds to only 0.2 volts generated across each diode—on the order of the typical built-in voltage for a Schottky diode. The practical limitations of a space power system are thus the large number of diodes needed, and the low voltage generated across each diode. The efficiency could also be improved by placing each diode inside a high Q resonant structure, or by using diodes with lower built-in voltage. However, either of these solutions alone would not solve the problem of the large number of required diodes.

As such there is a need for lens-like structures that will allow the number of diodes to be reduced.

BRIEF DESCRIPTION OF THE INVENTION

Briefly and in general terms, the disclosed technology, in one aspect comprises a rectenna structure comprising: a flexible, dielectric sheet of material; a plurality of metallic lenslets disposed on the sheet of material; and a plurality of diodes disposed on the sheet of material, each diode in said plurality of diodes being arranged at a focus of a corresponding one of said plurality of metallic lenslets.

In another aspect, the disclosed technology relates to a method of generating electrical power for use aboard an aircraft or a satellite, the method comprising: deploying a sheet of dielectric material in an orientation, the sheet of dielectric material being associated with, coupled to and/or forming a part of said aircraft or satellite, the sheet of dielectric material having a plurality of metallic lenslets disposed on the sheet of dielectric material and a plurality of diodes disposed on or adjacent the sheet of dielectric material, each diode in said plurality of diodes being arranged at a focus of a corresponding one of said plurality of metallic lenslets, the diodes being coupled together for supplying electrical power for use by systems aboard said aircraft or a satellite, and directing the orientation of the sheet of dielectric material to receive incident radiation from a source of electromagnetic radiation.

BRIEF DESCRIPTION OF THE FIGURES

FIG. **1** depicts beaming microwave power to an orbiting satellite as an alternative to the use of traditional solar panels, batteries, and other power sources on the satellite.

FIG. **2** depicts another application for beamed RF power which includes airships that would supply cities with wireless services, for example.

FIG. **3** depicts an application where beamed RF power may also be used to power "slow-flight" micro-UAVs, which could be used for law-enforcement or surveillance, or investigations made at a hazardous site, for example.

FIG. **4** shows the geometry involved in equation [3], which equation can be used to determine the required diameters for the transmitting and receiving antennas.

FIG. **5** depicts radiation from a relatively larger being concentrated onto each diode, using, for example, a lightweight, planar resonant structure that may be printed on a thin, flexible plastic film.

FIG. **6** depicts a large plastic film, printed with metallic lens structures, and populated with rectifier diodes, (not shown) that would serve as a lightweight collector for microwave power. Such a structure could be built to cover tens of meters with minimal weight. The use of printed metallic lenses would reduce the number of diodes, and would increase the voltage across each diode for improved efficiency.

FIG. **7** depicts an embodiment where power is focused onto a sparse array of diodes using a lightweight plastic film that is patterned with metallic lenses.

FIG. **8***a* depicts a coplanar antenna on a diode-tuned surface and experiments using such tunable textured surfaces has led the inventor named herein to believe that planar lens structures can focus power onto a coplanar antenna, yielding a completely flat structure.

FIG. **8***b* is a graph of the gain for uniform surface impedance.

FIG. **8***c* is a graph of the gain for an optimized, non-uniform surface.

FIG. **9** is a graph depicting the effective aperture for an antenna mounted on an optimized impedance surface can be nearly equal to the entire surface area. The effective aperture size assumes the expected cosine function when optimized for different elevation angles. The effective aperture for a uniform surface is shown for comparison. By optimizing a textured surface, one can make a large-area, planar collector for microwave radiation.

FIG. **10** is a plan view of a lightweight, high-efficiency rectenna system based on printed metallic lenslets, and a sparse array of rectifier diodes. The lenslets collect power over many square wavelengths and route it to the diodes. This provides greater power per diode (thus improving efficiency) and also reduces the diode count to a practical number.

FIGS. **10***a*, **10***b* and **10***c* are side elevation views taken through the structure depicted in FIG. **10**.

FIG. **11** is a side elevation view of an embodiment with a ground plane spaced from the lenslets using a honeycomb-like structure.

FIG. **12** depicts an array of metal plates with a period of one-quarter wavelength, and features that vary on a length scale of one wavelength, with radial symmetry.

FIG. **13** depicts an array of lenses depicted by FIG. **12**, each lens having a diode at its center, with those diodes being connected by DC lines.

FIG. **14** is similar to FIG. **10***b*, but with a DC line being shown on a reverse side of the dielectric sheet.

DETAILED DESCRIPTION

A problem in trying to develop a practical earth to space power transmission system is that the voltage across diodes used in a rectenna has not been sufficient in a prior art rectenna to be of practical use to such an application.

However, the voltage across each diode **25** can be increased while reducing the number of diodes by using a lens-like structure or lenslet **40**, shown in FIG. **5**, to concentrate power from a large area over a small number of diodes **25** in an array of lenslets **40**. For example, if one wanted to generate 20 volts across each diode **25**, then the incident power from 40 square wavelengths, or a 2-cm diameter area, needs to be collected. This would not only boost the voltage across each diode—and also the diode's efficiency—it would also reduce the number of diodes to about 3 million for the example described above, which equates to about 100 wafers' worth of diodes. Further reductions in the number of diodes required could be achieved with an even larger collection area per diode. Each lenslet **40** comprises a geometric array of electrically conductive patches **42** disposed on a supporting surface. The conductive patches **42** are preferably formed by thin, individual metallic patches formed on a supporting surface, such as, for example, a thin sheet of a plastic material.

Of course, a traditional dielectric lens would be impractical, but a metallic lens imprinted on a lightweight plastic film **50**, which may be unfolded over a large area and could be utilized in a space environment, is practical. This concept for building a practical microwave space power system is illustrated in FIG. **6** where ground-based radiation is represented by arrows A. The thin plastic film **50** would be patterned with sub-wavelength resonant metallic regions or lenslets **40**, which would focus the incoming power to a sparse array of diodes **25**. Such a film **50** could be made by the tens of meters, but nevertheless would have minimal weight. The metallic lenses would serve the dual purposes of minimizing the number of diodes **25** required, while also improving the efficiency by increasing the voltage across each diode **25**.

In accordance with the presently disclosed technology, a structure having a thin plastic film **50** that is covered with a plurality of thin metal patterns, each pattern comprising a plurality of small electrically conductive patches **42** forming a lenslet **40**, is disclosed. This technology may be used in applications such as the earth to space power transmission system discussed above. Each metal pattern or lenslet **40** is made such that it behaves as a planar lens, with a focal length of zero. That is, it focuses the incoming power in such a way that a relatively high energy field is created at one point on the surface of the lens **40**. The high-energy field has a higher energy than the average energy density of the electromagnetic waves impinging the plastic film **50**. The creation of the high-energy fields allows a rectifier diode **25** to be placed at the focus or center of the high-field location, so that all of the power impinging on the lens **40** is rectified by that diode **25**. This results in two improvements over existing rectenna designs: (1) It requires far fewer diodes, and (2) it allows the voltage per diode to be higher, which results in more efficient operation. As will be seen, an embodiment of the present invention includes the combination of a planar lens and a sparse array of rectifier diodes to create a lightweight, efficient rectenna.

The design of the planar lens can be summarized as follows: (1) assume that the plastic film **50** is preferably planar and is patterned with metallic or other electrically conductive patches **42** that can be considered as resonators, with a certain resonance frequency. (2) Characterize the patches **42** in terms of scattered field (magnitude and phase) for various frequencies with respect to the resonance frequency. (3) Choose the condition that the fields from all of the metal patches **42** should add up in phase at a single point at the focus of a lens **40**, or alternatively choose some other point on the lens. (4) Build a scattering matrix that describes the field at the chosen point on the lens, as a function of the incoming field. This must include the interaction among the various metallic patches. (5) Optimize the resonance frequencies of the metal patches **42** so that the field at the chosen point is a maximum. Of course, diodes **25** would be placed at the focal points of the lenses **40**.

Concentrating microwave power from a large area (several tens of square wavelengths) onto a single device, using a thin, patterned metal film can be done in several ways, including by using a non-uniform frequency selective surface (FSS). These structures have been studied for many years for filtering radomes, and other applications. A non-uniform FSS could be designed to have lens-like behavior, and focus incoming waves from a large area onto a single receiving antenna. This is similar to the Fresnel zone plate that is known in optics, but it can have high efficiency because the metal patterns can be designed to provide only a phase shift, with minimal absorption. A series of microwave lenslets **54** could be patterned over a large area of thin plastic film **50**, as shown in FIG. **6**, to focus the low-density microwave power onto a sparse array of diodes **25**.

One drawback of the traditional FSS approach, shown in FIG. **7**, is that it is not uniplanar, because of the need to focus over a distance "t" which would be roughly equal to the diameter of the lenslets **40**. It would be difficult to unfold such a structure over an area of many square meters while maintaining the required spacing "t" within suitable tolerances for efficient energy collection.

An alternative is to consider structures where the receiving antennas and the diodes are arranged in a coplanar alignment with the metallic lens structures. This concept has already been demonstrated at HRL Laboratories of Malibu, Calif., through work with tunable, textured electromagnetic surfaces. See, for example, the patent applications mentioned above. A metallic surface texture can be made (through proper optimization) to focus power from many square wavelengths, onto an antenna that is coplanar with the textured surface, as illustrated in FIG. **8**. The metallic surface can be quite thin and for most applications, the thinner the metal on the metallic surface the better (due to weight considerations). The experiments at HRL Laboratories involved a diode-tuned impedance surface consisting of many small metallic patches linked by varactor diodes. See the paper by Sievenpiper, 2003, supra, and the patent applications referred to above. Experiments using tunable textured surfaces suggest that planar lens structures can focus power onto a coplanar antenna, yielding a completely (or essentially) flat structure as shown in FIG. **8***a*. The structure of FIG. **8***a* can be made so flat that the antenna and tunable textured surface is nearly imperceptible to one's fingers. Of course, the structures can be more pronounced in some embodiments (so that they would not generally be called flat), but, generally speaking, flat or nearly flat structures would be preferred in most applications, particularly where the plastic film **50** is to be unfolded someplace, such as in space, where human intervention (due to snags and the like), may well not be possible, convenient or desirable.

FIG. **8***b* is a graph of the gain for uniform surface impedance while FIG. **8***c* is a graph of the gain for an optimized, non-uniform surface. Using this surface with a coplanar antenna, it was determined that the pattern of capacitance between the metallic patches could be optimized to increase the gain of the antenna mounted on the surface. In this way, the effective aperture size could be extended to cover the entire area of the surface, as plotted in FIG. **9**, which indicates that by proper design of a non-uniform impedance surface, power can be collected over a relatively large area (for example a relatively large area may be as large as perhaps hundreds or thousands of square of wavelengths of the impinging radiation), and routed to a single diode on the non-uniform impedance surface for rectification. For RF space power applications, the surface texture would consist of a lattice of fixed capacitors, built into metallized plastic. The capacitors are formed edge to confronting edge of the plates making up each lens. The afore-mentioned capacitors come from the fact that there are small metallic plates that are very close together. These are edge-to-edge capacitors, rather than conventional parallel plate capacitors. Any two conductors that are brought near each other will have some amount of capacitance. A ground plane is not needed here, but it could be used to provide improved efficiency, at the expense of greater weight. The values of the capacitors and the shape of the metal particles would be determined by electromagnetic simulations, and an optimization algorithm.

The results described above with reference to FIGS. **8***a*–**8***c* are for a two-layer structure containing vertical metallic vias—a high-impedance surface—that was built using printed circuit board technology as described in my issued U.S. patents and published U.S. patent applications. Lighter weight structures are needed in order to make this general concept practical and sufficiently lightweight for convenient use in space or even for use on an airship such as the airship shown in FIG. **2**. For example, the planar lenslets **40**, the collection antennas **60**, and the rectifier diodes **25** should preferably be built on a single surface that would preferably be printed on a single-layer plastic, dielectric film. Of significant importance would be the elimination of the vertical vias, and preferably the ground plane itself, leading to an entirely uniplanar structure. Simple uniplanar structures have been studied (See Yang, 1999, supra), but techniques for optimizing complex non-uniform surfaces need to be developed.

Furthermore, if the ground plane is eliminated, methods for minimizing transmission through the structure also would need to be considered. The structure could be analyzed as a complex parasitic array, where the individual patches in the patterned metallic surface could be considered as parasitic antennas. Their shape would be optimized so that the scattered power from each of them would be maximized at one point, where the rectifier diodes would be placed.

A microwave structure embodiment is depicted by FIG. **10**. FIGS. **10***a*, **10***b* and **10***c* provide section views through the embodiment depicted by FIG. **10**. In this embodiment a lattice of printed metallic lenslets **40**, each formed by arrays of thin metal patches **42**, focus power onto a sparse array of rectifier diodes **25**, which could be coplanar with the lenslets or mounted on the adjacent patches **42** as shown by FIG. **10***c*. DC power lines **65** (which are preferably incorporated into the structure) could then carry power from diodes **25** to the satellite **10**, for example, for distribution to the onboard electronic systems. The entire rectenna could be printed on a thin, lightweight, plastic film **50**, which could be unfolded to cover an area comprising many square meters. Like all rectennas, it would not need to assume a particular shape, because rectification is done right at each antenna element. However, since each lenslet would provide some directivity, the surface would need to be roughly pointed toward (i.e. be orthogonal to) the source of energy, such as the ground station **10** source. The required pointing accuracy, among other things, would govern the size of the lenslets **40**.

A ground plane may be helpful in some embodiment. It could increase the efficiency, by not allowing any energy to pass through the structure. The metallic pattern on the top of film **50** would be qualitatively similar to that without the ground plane, but in detail it would probably be a different pattern to compensate for the presence of the ground plane. The ground plane would have to be separated from the top metal patterns by some distance, typically 1/100 to 1/10 wavelength, depending on the tolerances allowed in the manufacturing of the metallic patterns. (This is not due to the tolerance of the film thickness. It is due to the fact that the overall thickness will affect the bandwidth. If the bandwidth is very narrow, then the metallic patterns will have to be defined very accurately to get the capacitance right.) In order to allow some spacing, but not to have a very heavy structure, an embodiment with a ground plane **44** may be ribbed, air-filled structure **46**, such as that seen in FIG. **11**. This might be similar to flexible "bubble wrap", or a rigid honeycomb-like dielectric that is commonly used in airframes and other such things.

In summary, the rectenna consists of a rectifying diode **25** and a generally planar lens structure **40**. The lens structure comprises a thin dielectric (such as plastic) sheet **50** that is patterned with metallic regions **42**. The metallic regions **42** scatter electromagnetic energy, and they are arranged so that the collective scattered energy from all of them is focused into the diode **25**. Each rectifying diode **25** is attached between two adjacent ones of the metal regions **42**. The diodes **25** are also attached to long conductive paths **46** (wires) that traverse the entire width of the structure, or are otherwise routed so that they supply current to a common location (such as an edge) where it may be collected and used to supply electrical power to a satellite or other device. The wires **46** are preferably coplanar with the metal patches **42** that make up the lens **40**, and they are preferably oriented transverse to the expected polarization of the energizing RF field, so that they have a minimum scattering effect. The metal pattern of the lens **40** can also be optimized to account for the scattering of the wires **46**. The lens **40** and indeed the thin dielectric sheet **50** preferably have a planar configuration and indeed the rectenna, when designed, will very likely be assumed to have a planar configuration in order to simplify its design (see the foregoing discussion). But those skilled in the art should appreciate the fact that the sheet **50** may well assume a non-parallel configuration in use, either by design or by accident. If designed for a planar configuration, the extent by which the in-use sheet **50** deviates from a planar configuration will adversely affect its effectiveness. But if the in-use design is close to being planar, the loss in efficiency is likely to be very small. Of course, the rectenna can be designed initially with a non-planar configuration in mind, but a non-planar configuration will doubtlessly complicate finding a desirable arrangement of the patches **42** for the various lenslets **40**. Making an assumption that the sheet **50** and the lenslets **40** will all be planar should simplify the design of the rectenna significantly.

The lenses (or lenslets) **40** are ideally designed and optimized using a computer. A random collection of scatterers is simulated, and the collected power is calculated using an electromagnetic solver. The sizes, shapes, and locations of the scatterers are varied according to an optimization method. Such methods are known to those skilled in the art, and include the method of steepest descent, genetic algorithms, and many others. The geometry that provides the greatest power to the diode **25** is then apt to be chosen as the ideal structure.

Such methods are good for determining the best geometry when nothing is known about that geometry beforehand. However, in the case of the present invention, much is known about the required geometry, and one can design a simple structure by hand. The preferred design method is then to start with a known good structure using the calculations described below, and then to optimize it using a computer as described above.

It can be shown that a wave having wave vector k_0, propagating on a periodic structure with effective refractive index n_{eff} will be scattered by the periodicity of that structure k_p to an angle θ given by:

$$\theta = \mathrm{Sin}^{-1}\left(\frac{k_0 n_{eff} - k_p}{k_p}\right) \qquad [4]$$

The planar lens structure should be designed so that energy scatters from the normal direction (θ=0°) into the plane of the surface where the diode is located. Assuming that the dielectric layer is thin, we have $n_{eff}=1$, so we are left with $k_p=k_0$. Therefore, the periodicity of the structure should be roughly one free-space wavelength.

In order to have independent control over the magnitude and phase of the radiation from the feed point, (or conversely in the present case, the collected energy at the diode **25**) it is necessary to have the periodicity be much greater. For independent control over two parameters, the array should be oversampled by a factor of at least two, which means that the individual metal patches **42** should be spaced at most one-quarter wavelength apart, with their properties varying periodically on a length scale of one wavelength. The structure should have close to radial symmetry, so that energy is scattered inward toward a central point. However, the symmetry can vary from perfect radial symmetry to account for polarization effects (leading to a slight deviation which has mirror symmetry) or for practical reasons due to the discrete nature of the individual patches **42**. An example of such a structure is shown in FIG. **12**.

FIG. **12** depicts an array of metal plates **42** located on centers spaced with a period of one-quarter wavelength, and the features thereof (size in this embodiment) vary on a length scale of one wavelength, with radial symmetry. The scattered energy from the metal plates **42** combines coherently at the diode **25** located at the center of the geometric pattern formed by plates **42**.

This single planar lens **40** consists of metal patches **42** having a periodicity of one-quarter wavelength, and having properties (the patch size in this embodiment) varying with a period of one wavelength. The planar lens **40** shown has a diameter of about four wavelengths. It collects power over its entire surface, and directs it toward the diode **25** at the center of the pattern, which diode is preferably connected between a pair of the closest patches **42**. This lens **40** forms a single element of a larger array **65**, shown in FIG. **13**, in which the diodes **25** are also connected in parallel by rows.

FIG. **13** depicts an array of planar lenslets or lenses **30**, each having a diode **25** at the center thereof, with those diodes **25** being connected by DC lines **46**. The lines are preferably oriented transverse to the electric field of the incoming radiation, so that they do not interfere significantly with the scattered waves. They can be printed on the same side of the sheet **50** (see FIG. **10***b*) as the metallic patches **42**, in which case the metal pattern of the lines **46** would simply be combined with that of the patches **42**, or they can be printed on the reverse side of sheet **50**, and attached to the diodes **25** by small metal plated via holes **48** in the plastic sheet **50**, as shown by FIG. **14**.

This design requires far fewer diodes than do conventional rectennas, because the diodes **25** are spaced every four wavelengths, rather than every half-wavelength. The result is a factor of close to 64 times reduction in the number of required diodes, and a corresponding factor of 64 times increase in the voltage generated per diode. This is particularly useful in cases where the incoming power density is low (such as space applications), where it would otherwise be difficult to get the induced voltage above the diode threshold voltage. Thus, this design also has higher efficiency due to the greater induced voltage at lower power levels.

Having described this technology in connection with certain embodiments thereof, modification will now doubtlessly suggest itself to those skilled in the art. As such, the protection afforded hereby is not to be limited to the disclosed embodiments except as is specifically required by the appended claims.

What is claimed is:

1. A rectenna structure comprising:

a sheet of a dielectric material;

a plurality of metallic lenslets disposed on the sheet of dielectric material; and

a plurality of diodes disposed on or adjacent the sheet of dielectric material, each diode in said plurality of diodes being arranged at a focus of a corresponding one of said plurality of metallic lenslets.

2. The rectenna structure of claim **1** wherein the metallic lenslets each comprise a geometric arrangement of metallic patches.

3. The rectenna structure of claim **2** wherein the focus of each lenslet corresponds to a center of the geometric arrangement of metallic patches comprising the lenslet.

4. The rectenna structure of claim **2** wherein the rectenna is designed to be responsive to incident radiation for converting the incident radiation to electrical energy and wherein metallic patches in each of said geometric arrangements have centers which are spaced from centers of neighboring metallic patches by a distance equal to one-quarter wavelength of said incident radiation.

5. The rectenna structure of claim **4** wherein the patches in each of said lenslets have a property that varies along a radial direction from the focus of the lenslet with a period equal to one wavelength of said incident radiation.

6. The rectenna structure of claim **5** wherein the property that varies along a radial direction from the focus of the lenslet is the geometric size of the individual patches.

7. The rectenna structure of claim **6** wherein the geometric arrangement is a hexagonal arrangement.

8. The rectenna structure of claim **7** wherein the individual patches each have a hexagonal shape when viewed in a plan view.

9. The rectenna structure of claim **6** wherein the geometric arrangement is a square arrangement.

10. The rectenna structure of claim **6** wherein the metallic lenslets have maximum dimension in a plan view thereof that is equal to four wavelengths of said incident radiation.

11. The rectenna structure of claim **2** wherein the geometric arrangement has two orthogonal axes of symmetry and wherein at least selected ones of said metallic patches associated with a particular geometric arrangement do not intersect either of the axes of symmetry of said particular geometric arrangement but rather are separated from the axes of symmetry of said particular geometric arrangement by predetermined distances.

12. The rectenna structure of claim **2** wherein the geometric arrangement is hexagonal.

13. The rectenna structure of claim **12** wherein the patches disposed in the hexagonal geometric arrangement are individually hexagonally shaped and are arranged in hexagonally shaped rings of hexagonally shaped patches, with neighboring rings comprising patches of different sizes.

14. The rectenna structure of claim **1** wherein each said lenses behave as a planar lens with a focal length equal to zero.

15. A method of making a rectenna structure comprising:

providing a sheet of dielectric material;

disposing a plurality of metallic lenslets on the sheet of dielectric material; and

disposing a plurality of diodes on or adjacent the sheet of dielectric material and arranging each diode of said plurality of diodes at a focus of a corresponding one of said plurality of metallic lenslets.

16. The method of claim **15** further including providing the metallic lenslets as a geometric arrangement of metallic patches.

17. The method of claim **16** further including arranging the focus of each lenslet to correspond with a center of said geometric arrangement of metallic patches.

18. The method of claim **15** further including designing the rectenna to be responsive to incident radiation for converting the incident radiation to electrical energy wherein metallic patches in each of said geometric arrangements have centers which are spaced from centers of neighboring metallic patches by a distance equal to one-quarter wavelength of said incident radiation.

19. The method of claim **18** wherein the patches in each of said lenslets have a property that varies along a radial direction from the focus of the lenslet with a period equal to one wavelength of said incident radiation.

20. The method of claim **19** wherein the property that varies along a radial direction from the focus of the lenslet is the geometric size of the individual patches.

21. The method of claim **20** wherein the geometric arrangement is a hexagonal arrangement.

22. The method of claim **21** wherein the individual patches each have a hexagonal shape when viewed in a plan view.

23. The method of claim **20** wherein the geometric arrangement is a square arrangement.

24. The method of claim **20** wherein the metallic lenslets have maximum dimension in a plan view thereof that is equal to four wavelengths of said incident radiation.

(57) ABSTRACT

A method and apparatus for performing far-field power extraction are presented. The method includes receiving an electromagnetic radiation signal, rectifying the signal to produce a direct current (D.C.) voltage and providing the D.C. voltage to a circuit. A far-field power extraction circuit includes an antenna for receiving an electromagnetic radiation signal, a rectifier for rectifying the electromagnetic radiation signal. The circuit may further include a charge pump for amplifying the rectified voltage, an impedance matching network for coupling the antenna to the rectifier and a feedback tuning circuit for optimizing performance of the extraction circuit.

FIELD OF THE INVENTION

The present invention relates generally to power extraction and more particularly to circuits and systems for extracting power from radio frequency (RF) signals.

BACKGROUND OF THE INVENTION

Devising efficient methods for extracting DC power from electromagnetic radiation has become an important necessity for a number of applications involving self-powered devices, such as Radio Frequency Identification (RFID) tags and bionic implants. The operating range of such self-powered devices has been severely limited by the failure of existing power extraction techniques to successfully extract power from radio frequency (RF) signals having relatively low power levels. The problem of extracting DC power from electromagnetic radiation has two basic parts: collecting the incident radiated power, and then converting the collected power to DC signals which are usable by the self-powered devices.

Converting RF energy from RF signals at different frequencies is a relatively difficult problem particularly when the RF signals have relatively low power levels. Fundamentally, this problem arises because frequency conversion is generally a nonlinear operation, but all practical systems are essentially linear for small signals. In addition, nonlinear devices normally used for rectification have exponential nonlinearities with relatively large "dead zones" near the origin, i.e., nonlinear devices can be non-responsive in response to signals having voltage and current levels which are close to zero. Severe constraints can also be imposed when it is desirable to provide a self-powered device which is relatively inexpensive and environmentally robust. This limitation precludes the use of exotic devices and structures.

SUMMARY OF THE INVENTION

A method and apparatus for performing far-field power extraction are disclosed. The method includes receiving an electromagnetic radiation signal, rectifying the signal to produce a direct current (D.C.) voltage and providing the D.C. voltage to a circuit. A far-field power extraction circuit includes an antenna for receiving an electromagnetic radiation signal, a rectifier for rectifying the electromagnetic radiation signal. The circuit may further include a charge pump for amplifying the rectified voltage, an impedance matching network for coupling the antenna to the rectifier and a feedback tuning circuit for optimizing performance of the extraction circuit.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be more fully understood from the following detailed description taken in conjunction with the accompanying drawings, in which:

FIG. **1** is a block diagram of a power extraction system;

FIG. **2** is a diagram of a broadband planar dipole antenna for RF power extraction;

FIG. **3** is a plot showing a reflection characteristic (into a 50Ω load) of the antenna shown in FIG. **2**;

FIG. **4** is a plot of the AC transfer characteristic of an input matching network for a loaded Q of 2;

FIG. **5** is a schematic diagram of a rectifier circuit including a nonlinear capacitor and a switching rectifier;

FIG. **6** is a plot of a rectification characteristic of the rectifier circuit shown in FIG. **5**;

FIG. **7** is a plot of the simulated response of the rectifier circuit of FIG. **5** in response to an input RF signal having a peak-to-peak amplitude of 0.5 V;

FIG. **8** is a schematic diagram of a charge pump cell;

FIG. **9** is a plot showing the stimulated response of the charge pump-switching rectifier combination shown in FIG. **1** in response to an input RF signal having a peak-to-peak amplitude of 0.55 V;

FIG. **10** is a schematic diagram of a solar cell circuit;

FIG. **11** is a schematic diagram of a controller; and

FIG. **12** is a block diagram of an RF power extraction system.

DETAILED DESCRIPTION OF THE INVENTION

The present invention comprises various combinations of different circuits and techniques to efficiently extract power from electromagnetic signals having relatively low electromagnetic field strengths in the far field of the transmitter, thereby substantially reducing the power threshold required for operation of self-powered devices.

Referring now to FIG. **1**, a block diagram of a system **10** for extracting power from electromagnetic radiation includes an antenna **20** for receiving a radio frequency (RF) signal from which direct current (DC) power will be harvested. A matching network **30** is coupled to the antenna **20** to impedance match the antenna **20** to the remainder of the system, thereby obtaining efficient power transfer. A switched rectifier **40** operates on the impedance matched differential RF signal and converts the signal to one or more DC levels. The output of the switched rectifier **40** is coupled to a group of charge pumps **50**, which increase the DC levels of the voltage. The output of the charge pumps is coupled across a load capacitor **60** to provide the DC output voltage. A feedback tuning circuit **70** is coupled to the output voltage and feeds into the impedance matching network **30** to provide continuous tuning of the impedance matching network to get the maximum possible DC output.

Referring now to FIG. **2**, the antenna **20** is shown. The antenna bandwidth is defined as the frequency range over which the reflection coefficient of the antenna into a specified load impedance is less than some specified value, typically −10 dB (VSWR=2). This antenna has improved bandwidth over a simple linear dipole, while occupying approximately the same area. In a preferred embodiment the antenna **20** thus comprises a wideband dipole antenna.

It should be appreciated that although a particular dipole antenna design is shown in FIG. **2**, it may be desirable to provide the antenna as a planar loop, dipole or fractal antenna. In one embodiment, the antenna **20** is provided on a flexible substrate. One objective for power collection applications is to provide a planar antenna on a flexible substrate that produces the maximum possible open circuit voltage V_{OC} across the antenna terminals **21** and **22** for a given incident field strength. In addition, the antenna design has to have sufficient bandwidth to withstand bending and proximity effects, such as attachment to a dielectric surface, without moving too far off resonance. Since passive RFID systems typically use backscatter modulation to communicate with the tag reader, another factor of interest is optimization of the Radar Cross Section (RCS) modulation capabilities of the antenna.

To address these issues, the use of one or more of planar loop, dipole, bow-tie and fractal antennas is presented. Loop antennas are advantageous because most proximity (near field) effects in practice are caused by dielectric materials. Since the near field energy of loop antennas is primarily stored in the magnetic field, they are typically less susceptible to these effects than other antenna types. Bow-tie antennas are desirable when a large impedance matching bandwidth is desired, but typically require large amounts of area in order to achieve this bandwidth. Fractal antenna structures are of interest in this application since they allow the bandwidth to be increased without consuming more area, or by reducing the area required to achieve a given bandwidth. Photonic Band Gap (PBG) substrates which reduce losses due to surface wave propagation in the flexible substrate may also be utilized. PBG substrates have electrical properties (like dielectric constants) which are periodic functions of space. Solutions of Maxwell's equations in such a medium have a 'stop band', or forbidden frequency range, where no surface wave propagation is possible. This may be utilized in our application by making the stop band lie in the frequency range where the main surface wave modes propagate, thereby preventing energy loss due to such (undesirable) modes and improving the efficiency of power extraction.

Referring now to FIG. **3**, a plot **25** of a simulated reflection characteristic for the antenna **20** is shown. In graph **25**, S_{11} is the reflection coefficient of the antenna and the substrate material used for simulations was FR-4. When simulated with a commercially available Method of Moments (MoM) based field solver, and using a criteria of a voltage standing wave ratio (VSWR) of two ($VSWR \leqq 2$) this antenna **20** exhibited a fractional bandwidth of approximately 40% at a center frequency of about 900 MHz. In this implementation, the antenna occupied an area of approximately 5"×2.5".

Referring again to FIG. **2**, another technique used in performing far-field RF power extraction comprises utilizing package parasitics to increase the input voltage levels to the rectifier. The far field case, when the input amplitude of the RF signal is not large enough to efficiently operate typical rectifying devices such as Schottky diodes are of particular interest. To overcome this problem, the high-Q input matching network **30** is used to passively amplify the input RF voltage. The inductance L and capacitance characteristics C(V) of network **30** are adjusted to include the effects of parasitic inductances and capacitances introduced by the chip packaging. In this way, a use for these normally unwanted parasitic characteristics has been found, as they now function as part of the matching network **30**. Of course, increasing the Q also decreases the frequency range over which the system can operate and increases its sensitivity to environmental conditions, which cause the resonant frequency to drift with time. This necessitates the use of active resonant frequency control. This is implemented by the feedback tuning network shown in FIG. **1**.

Another technique used in performing far-field RE power extraction comprises using traveling wave architectures for distributed voltage amplification and rectification. The matching network **30** is provided having both high voltage gain and high bandwidth at the input of the rectifier by using a cascade of exponentially tapered inductor-resistor-capacitor (L-R-C) transmission line segments. Each segment acts like a low pass filter with a certain Q and cutoff frequency. All segments have essentially the same Q, but have exponentially tapering cutoff frequencies. The cutoff frequency of the n-th section is given by:

$$f_n = exp(-n/N_{nat})$$

where f_n and N_{nat} are constants. Such a technique is useful for attaining high gain from many low-gain stages.

Referring now to FIG. **4**, a graph **35** which shows the AC transfer characteristic of the input matching network **30** for a loaded Q of 2 and a resonant frequency of 900 MHz is shown. The curve shows that a maximum output is achieved at approximately 900 MHz. The input to the matching network is assumed to be the antenna, and its output is fed to the switched rectifier.

Referring now to FIG. **5**, a rectifier circuit **40** is shown. One aspect of the present invention for performing efficient power extraction comprises using parametric-amplifier-like topologies and capacitive nonlinearities for rectification instead of exponential resistive nonlinearities. Exponential resistive nonlinearities (e.g., diodes) have traditionally been used for rectification but are unsuitable at low power levels. To solve this problem, parametric-amplifier-like topologies and capacitive nonlinearities are used. FIG. **5** shows how a nonlinear capacitor (e.g. a varactor) **41** is used for rectification. The varactor **41** (which can be a reverse-biased PN junction or a MOS capacitor) has a capacitance characteristic C(V), where V is the voltage of the control terminal. V is varied at the same frequency as the input RF signal. The RF signal is applied differentially, and, as an example, V may be tied to the upper plate of the varactor. In that case, C(V) will be different on the positive and negative halves of the RF signal cycle.

Inductors **42** and **43** and varactor **41** form a high-Q circuit and are chosen to resonate at the input frequency for some value of V. Since V varies as the RF, the resonant frequency and gain of the resonator will also be different on the positive and negative halves of the RF cycle. This asymmetric signal gain leads to the development of a DC component V_{DC} of voltage across the capacitor **46**, i.e., rectification.

The power extraction system can be adaptively adjusted for optimal performance by using floating gate transistors as adaptive elements. The threshold voltage of floating gate transistors can be changed by adding or subtracting charge from the floating gate. A lower threshold voltage improves the performance of the switching rectifier and charge pumps described in the following sections by increasing the rectified current for a given input RF amplitude.

In addition, the highest Q that can be used for the input LC tank shown in FIG. **2** is limited by resonant frequency variations caused by environmental factors and manufacturing tolerances. This limits the passive voltage gain obtainable from the tank. To overcome this problem, a high-Q system which maintains a constant resonant frequency by adapting the C(V) characteristic appropriately is utilized. This can be done by using a floating gate MOS capacitor for C(V).

Still another technique for performing far-field RF power extraction requires using switching rectifiers to avoid voltage drops associated with diode rectifiers. By using the differential RF inputs to operate transistors as switches and not as diodes, the threshold voltage drop associated with diode rectifiers is reduced considerably. FIG. **5** shows a circuit that achieves this. When the phase of the RF input is such that gate of the upper PMOS transistor **44** is low, it turns on, drawing current from the high side of the RF input, thereby charging the load capacitor **46**. The other transistor **45** is off during this phase. During the opposite RF phase, the roles of the two transistors are reversed, but the load capacitor is still charged upwards. The circuit thus acts as a full wave rectifier and charges the load capacitor C_L **46** towards the positive envelope of the input RF voltage V_{RF} sin(ωt). The final rectified DC voltage is determined by the resistance of the transistors and the load resistance connected to the output. It should be evident that by replacing the PMOS transistors with NMOS ones, the charging direction of the load capacitor can be reversed, i.e., charge can be made to flow out of the load capacitor, thereby decreasing the output voltage. Thus by adding a pair of NMOS devices **144**, **145** in parallel with the PMOS pair **44** and **45**, a negative voltage (referenced to the common mode voltage of the RF input) is generated, giving a total output DC voltage of approximately $2V_{RF}$ Note that MOSFET devices, being truly bidirectional devices, are ideally suitable for this circuit, where they are operated as switches This makes the integrated implementation of the circuit using standard low cost IC fabrication processes, such as CMOS, feasible.

FIG. **6** comprises a graph **48** which shows the simulated rectification curve **49** for the nonlinear capacitance when it was implemented as a MOS capacitor in a 0.5 μm CMOS process. The RF input amplitude was V_{RF} at 900 MHz. It can be shown that if the MOS devices operate in the sub-threshold region, this technique, which works by parametrically modulating the capacitance of a nonlinear capacitor **41**, allows the DC current charging the load capacitor C_L **46** to increase by a factor of cosh

$$\left(\frac{\kappa V_{DC}}{V_T}\right),$$

where K is the sub-threshold body bias coefficient and the thermal voltage

$$\left(\frac{\kappa V_{DC}}{V_T}\right),$$

FIG. **7** shows the results of a SPICE simulation **140** of the switching rectifier implemented in a 0.5 μm CMOS process with W/L=300 for both PMOS and NMOS devices. The input RF voltage amplitude V_{RF} was 0.5 V at 900 MHz. The charging time for a load capacitance C_L =50 pF was 1 μs.

Another technique for performing far-field RF power extraction uses charge pumps to increase the rectified output voltage. Since the input RF amplitude is extremely low (insufficient to operate the circuitry needed by the tag), charge pumps are used to increase the output DC voltage. FIG. **8** shows a single charge pump cell **50** using cross-coupled charge transfer switches. The differential RF input voltages ϕ and $\bar{\phi}$ are used to pump charge unilaterally through the pump capacitors C_P **55**, **56**, thus making $V_{OUT}>V_{IN}$. The circuit works as follows. When ϕ is high (=V_{RF} in this case), the bottom PMOS transistor **54** and the upper NMOS transistor **51** are turned on, while the other two transistors **52** and **53** are turned off. The other end of the pump capacitor **56** connected to ϕ is charged to its previous value (=V_{IN})+V_{RF} Current flows through the PMOS transistor **54** from this node, charging up the output towards (approximately) $V_{IN}+V_{RF}$. At the same time, the upper NMOS transistor **51** charges the other end of the pump capacitor **55** connected to $\bar{\phi}$ to V_{IN} The whole procedure is repeated during the opposite phase, when the RF input polarities are reversed. During this phase, the upper PMOS transistor **52** and the lower NMOS transistor **53** turn on, the other two transistors **51** and **54** turn off and the output is again charged towards $V_{IN}+V_{RF.}$

Ideally, $V_{OUT}=V_{IN}+V_{RF}$, i.e., a single cell acts as a voltage adder—it adds the RF amplitude to the input voltage. By cascading N of these cells in series, the output voltage is increased under no load conditions to $(N+1)V_{RF}$, where the input voltage to the first cell is assumed to be V_{RF}. Practically, parasitic capacitances to ground at the charge pumping nodes and increasing body bias effects on the NMOS devices limit the available voltage gain. This assumes that a typical n-well CMOS process is being used. This limitation can be removed if a more expensive dual-well process is used instead. In addition, by reversing the input and output terminals, the same circuit can be used to pump charge in the reverse direction and thereby generate large negative voltages. By combining charge pumps pumping in opposite directions with the switching rectifier described previously (which is assumed to generate approximately 2 V_{RF} across its outputs), an output DC voltage of $2(N+1)V_{RF}$ can be generated.

FIG. **9** shows the result of a SPICE simulation **57** of the switching rectifier **40** of FIG. **5** combined with the charge pump **50** shown in FIG. **8** implemented in a 0.5 μm CMOS process. Width (W)/Length(L)=60 for the devices in the switching rectifier, the pump capacitance C_P=1 pF and 2 cascaded cells were used to pump charge in each direction (N=2). The overall system was similar to that shown in FIG. **1**, with C_L=10 pF. The input RF amplitude V_{RF} was 0.55 V at 900 MHz.

The apparatus may utilize solar and other sources of ambient power for starting up the power collection module. For best performance, the power collection module can adapt to changing environmental conditions, for example by automatically adjusting the resonant frequency of the antenna using a feedback tuning network (shown in FIG. **1**). However, such adaptation loops consume power, which may not be available from the transmitted RF. To ensure startup power to run the adaptation loops, alternative sources of ambient power (apart from the transmitted RF) may be used. The amount of power required from these sources is small (typically in the nano watt range) since the system only needs to adapt slowly (time scale of milliseconds to seconds) and can thus be designed to have very low power consumption. Promising power sources include solar radiation (utilizing light energy using on-chip solar cells), ambient mechanical vibrations (using MEMS transducers), thermal gradients (using thermoelectric materials) and the like. FIG. **10** shows a solar cell structure **150** which can be used to provide startup power for the power collection module. The solar cell structure uses 3 solar diodes **152** in series to charge load capacitor **154**, thereby providing a D.C. voltage across the load capacitor **154**.

A feedback tuning network **70** is shown in FIG. **11**. The objective is to maximize the output DC voltage of the system, subject to a poorly known and possibly time varying open circuit RF amplitude across the antenna terminals. The primary cause of this is antenna resonant frequency variations. The resonant frequency (and other properties, such as the radiation pattern) of the antenna on the power collection module can vary by significant amounts because of variations in nearby environmental conditions. One way to minimize the effects of this variation is to use a broadband antenna, but this lowers the input Q and decreases the power up range. To prevent this, a feedback controller **70** is used to regulate the antenna resonant frequency (FIG. **11**). The controller uses derivative-based control to regulate the antenna resonant frequency. The controller comprises a state machine which operates on the temporal derivative of the rectified RF voltage and tries to keep it positive, i.e., increasing in time. The controller outputs a voltage which is used to control the capacitance of a MOS varactor, thereby controlling the resonant frequency of the antenna.

The controller shown in FIG. **11** can be implemented using subthreshold CMOS logic and consumes very little power. The controller can be powered off the rectified RF supply or from an alternative source of ambient energy, such as a solar cell. Two controllers running in different frequency ranges can be used to adapt the resonant frequency to variations that occur on different time scales. For example, a slow control loop could adjust to mechanical movement around the power collection module, while a faster loop could adjust to more rapidly varying quantities, such as multipath fading effects on the received RF signal.

The output of the switching rectifier (V_{ENV}, which is the DC voltage to be maximized) is provided to slope detector **210**. Slope detector **210** comprises a PMOS device **202** having a source coupled to the output of the rectifier and charge pumps (V_{ENV}), a gate coupled to the clock generator **260** and a drain coupled to storage capacitor **200**. The storage capacitor **200** is coupled between the drain of PMOS device **202** and a reference ground. A buffer **212** has a first input coupled to the output of rectifier and charge pumps and a second input coupled to the storage capacitor **200**, Buffer **212** provides a first buffer output and a second buffer output. A comparator **214** receives the buffer outputs and provides a comparator output. A latch **216** receives the output of comparator **214** and a clock input, and provides the slope detector output. In use, the output of the rectifier and charge pumps is sampled and held on the capacitor C_S **200** of slope detector **210**. This value is compared with the actual value of V_{ENV}. This operation is a discrete time approximation to the time derivative, and the output C of the slope detector **210** is a 1-bit estimate of the slope of V_{ENV}.

A predictor circuit **220** comprises a latch **222** receiving a clock input and a data input and providing an output to exclusive-or gate **224**. The exclusive-or gate **224** also receives the slope detector output and provides a predictor output which is also coupled to data input of latch **222**. In use, the predictor takes the current value of C, combines it with information about the previous correction made to the antenna resonant frequency and generates a control signal. This control signal is fed into an integrator **230**.

Integrator **230** comprises a PMOS device **232** receiving a positive bias voltage at a gate, having a source coupled to a reference voltage VP and providing an output at a drain. A second PMOS device **234** has a source coupled to drain of PMOS device **232**, a gate coupled to the output of predictor **220** and a drain providing an output of the integrator **230**. Integrator **230** further includes an NMOS device **238** receiving a negative bias voltage VN at a gate, having a source coupled to a reference ground and provides an output at a drain. The second NMOS device **236** has a source coupled to NMOS device **238**, a gate coupled to output of predictor **220** and a drain couple dot the drain of PMOS device **234** and also providing an output of integrator **230**.

The integrator **230** output voltage V_C controls the antenna resonant frequency by changing the capacitance of the MOS varactors **240**, **250** connected across the antenna output terminals. In the preferred implementation that is shown in FIG. **11**, the predictor control law is defined as:

$$\Delta V_{C,n+1} = C \oplus \Delta V_{C,n}$$

where $\Delta V_{C,n+1}$ is the new correction to be made to V_C, $\Delta V_{C,n}$ was the previous correction, and $\oplus$ denotes the logical XOR operation. This control law is that of a simple 'bang-bang' controller. Every time the controller makes a right decision (V_{ENV} increases and its slope C is positive), it repeats it on the next time step. Every time the controller makes a wrong decision (V_{ENV} decreases and its slope C is negative), it reverses its previous decision on the next time step. An oscillator (clock generator) **260** generates the sampling and timing signals for the rest of the system. Necessary current and voltage biases are generated by a bias generator **270**. Typically this takes the form of a supply-independent current reference circuit.

The physical structure of an RF power extraction system is shown in FIG. **12**. The input RF signal is captured by the antenna **20**. The antenna impedance is matched to the rest of the system using an appropriate matching networks **30**. The signal is then passively amplified using a high-Q resonator and fed to CMOS circuitry **80** which rectifies it and generates one or more DC voltages. These DC voltages are then used for powering other circuits on the chip **80**, such as an RFID transceiver. The entire system is disposed on a flexible substrate **90**.

The present application has focused on RFID tags operating in the UHF frequency band since it is of commercial importance, but the applicability of the present inventions is not confined to this application or frequency band. Since they are of a fairly general nature, the innovations described in thus application can be applied over a broad range of frequencies and power levels for various self-powered applications.

Currently, the minimum RF power threshold for self powered devices is in the 50–60 μW range. By way of implementing one or more of the techniques and circuits described above, this threshold is reduced to 3 μW or below. This results in a concomitant increase in the maximum read range by a factor of 4 over current designs.

Having described preferred embodiments of the invention it will now become apparent to those of ordinary skill in the art that other embodiments incorporating these concepts may be used. Additionally, the software included as part of the invention may be embodied in a computer program product that includes a computer useable medium. For example, such a computer usable medium can include a readable memory device, such as a hard drive device, a CD-ROM, a DVD-ROM, or a computer diskette, having computer readable program code segments stored thereon. The computer readable medium can also include a communications link, either optical, wired, or wireless, having program code segments carried thereon as digital or analog signals. Accordingly, it is submitted that that the invention should not be limited to the described embodiments but rather should be limited only by the spirit and scope of the appended claims. All publications and references cited herein are expressly incorporated herein by reference in their entirety.

What is claimed is:

1. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal; and

a switched rectifier coupled to the antenna, the switched rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output, the switched rectifier comprising at least one circuit element having a nonlinear capacitive characteristic.

2. The circuit of claim **1** wherein the antenna comprises at least one of a loop antenna, a dipole antenna, a bowtie antenna or a fractal antenna.

3. The circuit of claim **1** wherein

the at least one circuit element having a nonlinear capacitive characteristic comprises a non-linear capacitor.

4. The far-field power extraction circuit of claim **3** wherein the nonlinear capacitor is a varactor.

5. The circuit of claim **1** wherein the switched rectifier comprises:

a first P-type Metal Oxide Semiconductor (PMOS) switch; and

a second PMOS switch wherein the nonlinear capacitor is coupled to an RF source, a first lead of the nonlinear capacitor is coupled to a source of the first PMOS switch and coupled to a gate of the second PMOS switch, a second lead of the nonlinear capacitor is coupled to a gate of the first PMOS switch and a drain of the second PMOS switch and wherein a drain of the first PMOS switch is coupled to a source of the second PMOS switch and to a load capacitor.

6. The circuit of claim **5**, further comprising a first N-type Metal Oxide Semiconductor (NMOS) switch coupled in parallel to the first PMOS Switch and a second NMOS switch coupled in parallel with the second PMOS switch.

7. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal;

a switched rectifier coupled to the antenna, the rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output; and

an impedance matching network coupled between the antenna and the switched rectifier, the impedance matching network configured to match an antenna impedance with the remainder of the circuit, the impedance matching network comprising transmission line segments comprising inductor-resistor-capacitor line segments.

8. The circuit of claim **7**, further comprising a feedback tuning network coupled between the impedance matching network and the output voltage.

9. The circuit of claim **8** wherein the feedback tuning circuit comprises:

a bias generator;

a clock generator, wherein the bias generator is coupled to the clock generator;

a slope detector, wherein the slope detector is coupled to the switched rectifier and said charge pumps;

a predictor, wherein the clock generator is coupled to the slope detector and the predictor;

an integrator,

a first varactor; and

a second varactor wherein the integrator is coupled to the predictor and to the first and second varactors; wherein said first and second varactors are coupled to the antenna; and

wherein the feedback tuning circuit controls a resonant frequency of the antenna by changing a capacitance of the first and second varactors coupled across output terminals of the antenna.

10. The circuit of claim **9** wherein the slope detector comprises:

a PMOS device having a source coupled to the output of said switched rectifier, a gate coupled to the clock generator and a drain;

a storage capacitor coupled between the drain of the PMOS device and a reference ground;

a buffer having a first input coupled to the output of said switched rectifier and a second input

coupled to the storage capacitor, the buffer providing a first buffer output and a second buffer output;

a comparator receiving said first buffer output and the second buffer output and providing a comparator output; and

a latch receiving the output of the comparator and a clock input, the buffer providing a slope detector output.

11. The circuit of claim **9** wherein the predictor comprises:

a latch receiving a clock input and a data input and providing a latch output;

an exclusive-or gate receiving the latch output at a first input, receiving a slope detector output at a second output and providing a predictor output at the output and wherein the predictor output is coupled to the data input of the latch.

12. The circuit of claim **9** wherein the integrator comprises:

a first PMOS device receiving a positive bias voltage at a gate, having a source coupled to a reference voltage and providing an output at a drain;

a second PMOS device having a source coupled to the drain of the first PMOS device, a gate coupled to an output of the predictor and a drain providing an output of the integrator;

a first NMOS device receiving a negative bias voltage at a gate, having a source couple dot a reference ground and providing an output at a drain;

a second NMOS device having a source coupled to the first NMOS device, a gate coupled to an output of said predictor and a drain providing an output of the integrator.

13. The circuit of claim **9** wherein the first varactor comprises a PMOS device having a source and a drain coupled together and to the output of said integrator and having a gate coupled to said antenna.

14. The circuit of claim **9** wherein the second varactor comprises PMOS device having a source and a drain coupled together and to the output of the integrator and having a gate coupled to the antenna.

15. The circuit of claim **7** wherein the antenna and impedance matching network are responsive to radio frequency signals having a frequency of about 900 MHz.

16. The circuit of claim **7** wherein the transmission line segments have exponentially tapering cut-off frequencies.

17. The circuit of claim **7** wherein the impedance matching network comprises at least one inductor coupled between the antenna and the remainder of the power extraction system.

18. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal;

a switched rectifier coupled to the antenna, the rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output; and

a charge pump coupled to an output of the switched rectifier,

wherein the charge pump comprises:

a first N-type Metal Oxide Semiconductor (NMOS) switch, wherein an input voltage is coupled to a source of the first NMOS switch, and wherein a substrate of the first NMOS switch is coupled to ground;

a second NMOS switch, wherein the input voltage is coupled to a source of the second NMOS switch, and wherein a substrate of the second NMOS switch is coupled to ground;

a first P-type Metal Oxide Semiconductor (PMOS) switch; and

a second PMOS switch, wherein a drain of the first PMOS switch, a drain of said second NMOS switch, a substrate of the first PMOS switch and a substrate of the second PMOS switch are coupled together and provide an output voltage.

19. The circuit of claim **18** wherein the charge pump is coupled to a positive output of the switched rectifier.

20. The circuit of claim **18** wherein the charge pump is coupled to a negative output of the switched rectifier.

21. The circuit of claim **18** wherein the charge pump comprises:

a first pump capacitor, wherein a gate of the first NMOS switch is coupled to a drain of the second NMOS switch, a gate of the first PMOS switch, a source of the second PMOS switch, and to a first lead of the first pump capacitor; and wherein a second lead of the first pump capacitor is coupled to a first reference signal; and

a second pump capacitor wherein a gate of the second NMOS switch is coupled to a drain of the first NMOS switch, a gate of the second PMOS switch, a source of the first PMOS switch, and to a first lead of the second pump capacitor; wherein a second lead of the second pump capacitor is coupled to a second reference signal.

22. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal; and

a switched rectifier coupled to the antenna, the switched rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output, the switched rectifier comprising at least one of the group comprising a rectifier incorporating capacitive nonlinearities, a rectifier using transmission line segments, and a rectifier using one or more switching rectifier circuits,

wherein said switched rectifier incorporating capacitive nonlinearities comprises:

a variable capacitor;

a first P-type Metal Oxide Semiconductor (PMOS) switch; and

a second PMOS switch wherein said variable capacitor is coupled to an RF source, a first lead of said variable capacitor is coupled to a source of said first PMOS switch and coupled to a gate of said second PMOS switch, a second lead of said variable capacitor is coupled to a gate of said first PMOS switch and a drain of said second PMOS switch and wherein a drain of said first PMOS switch is coupled to a source of said second PMOS switch and to a load capacitor.

23. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal; and

a switched rectifier coupled to the antenna, the switched rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output, the switched rectifier comprising at least one of the group comprising a rectifier incorporating capacitive nonlinearities, a rectifier using transmission line segments, and a rectifier using one or more switching rectifier circuits,

wherein the transmission line segments have exponentially tapering cut-off frequencies.

24. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal;

a switched rectifier coupled to the antenna, the switched rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output, the switched rectifier comprising at least one of the group comprising a rectifier incorporating capacitive nonlinearities, a rectifier using transmission line segments, and a rectifier using one or more switching rectifier circuits; and

at least one charge pump coupled to an output of the rectifier,

wherein the at least one charge pump comprises:

a first N-type Metal Oxide Semiconductor (NMOS) switch, wherein an input voltage is coupled to a source of the first NMOS switch, and wherein a substrate of the first NMOS switch is coupled to ground;

a second NMOS switch, wherein the input voltage is coupled to a source of the second NMOS switch, and wherein a substrate of the second NMOS switch is coupled to ground;

a first P-type Metal Oxide Semiconductor (PMOS) switch; and

a second PMOS switch, wherein a drain of the first PMOS switch, a drain of said second NMOS switch, a substrate of the first PMOS switch and a substrate of the second PMOS switch are coupled together and provide an output voltage;

a first pump capacitor, wherein a gate of said first NMOS switch is coupled to a drain of said second NMOS switch, a gate of said first PMOS switch, a source of said second PMOS switch, and to a first lead of said first pump capacitor; and wherein a second lead of said first pump capacitor is coupled to a first reference signal; and

a second pump capacitor wherein a gate of said second NMOS switch is coupled to a drain of said first NMOS switch, a gate of said second PMOS switch, a source of said first PMOS switch, and to a first lead of said second pump capacitor; wherein a second lead of said second pump capacitor is coupled to a second reference signal.

25. A far-field power extraction circuit comprising:

an antenna configured to receive an electromagnetic radiation signal;

a switched rectifier coupled to the antenna, the switched rectifier configured to rectify the electromagnetic radiation signal received by the antenna to produce a direct current (D.C.) voltage at an output, the switched rectifier comprising at least one of the group comprising a rectifier incorporating capacitive nonlinearities, a rectifier using transmission line segments, and a rectifier using one or more switching rectifier circuits;

an impedance matching network coupled between the antenna and the switched rectifier, the impedance matching network configured to match an antenna impedance with the remainder of the circuit; and

a feedback tuning network coupled between the impedance matching network and the output voltage, the feedback tuning circuit comprising:

a bias generator;

a clock generator, wherein the bias generator is coupled to the clock generator;

a slope detector, wherein the slope detector is coupled to the switched rectifier and said charge pumps;

a predictor, wherein the clock generator is coupled to the slope detector and the predictor;

an integrator,

a first varactor; and

a second varactor, the integrator being coupled to the predictor and to the first and second varactors; wherein the first and second varactors being coupled to the antenna,

wherein the feedback tuning circuit controls a resonant frequency of the antenna by changing a capacitance of the first and second varactors coupled across output terminals of the antenna.

(57) **ABSTRACT**

A bias circuit operable to supply a bias current to a first transistor includes: a second transistor having a collector terminal connected to a first power supply; a first resistance element having one end connected to an emitter terminal of the second transistor and having the other end connected to a base terminal of the first transistor; a second resistance element having one end connected to the emitter terminal of the second transistor and having the other end connected to ground potential; at least one third resistance element provided between a base terminal of the second transistor and a second power supply; and a plurality of temperature compensation circuits connected to the base terminal of the second transistor which are operable to control a base potential of the second transistor so that the potential falls as a temperature rises.

FIG.9 PRIOR ART

RADIO-FREQUENCY POWER AMPLIFIER

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a radio-frequency power amplifier, and particularly to a radio-frequency power amplifier of which a bias circuit for supplying a bias current to the amplifying transistor includes a plurality of temperature compensation circuits.

2. Description of the Background Art

In recent years, due to the installation of various application functions in a mobile communication device such as a mobile phone, the number of components of the mobile phone tends to increase in accordance with the number of necessary components to control these functions. On the other hand, the mobile phone is miniaturized, and accordingly, it is necessary to miniaturize the components so as to increase the degree of integration of each component. However, some of the components may produce heat, and the higher the degree of integration of each component is made by miniaturizing the components, the more difficult it becomes to maintain a constant temperature in the mobile phone. Therefore, the components of the mobile phone are required to be stable with respect to temperature dependence.

In these circumstances, as a radio-frequency power amplifier, one of the components of the mobile phone, which amplifies the power of a radio-frequency transmitted signal, an HEMT (High Electron Mobility Transistor), which is stable toward temperature dependence, is used. However, this requires separately a negative voltage generator so as to control the gate voltage, and therefore hinders the miniaturization and the cost reduction of the mobile phone. As a result, conventionally, an HBT (Heterojunction Bipolar Transistor), which is used with a single power supply, is mostly used as a radio-frequency power amplifier. The bias circuit of a radio-frequency power amplifier using an HBT includes a temperature compensation circuit for compensating for the temperature characteristics of the diffusion potential between the base and emitter.

FIG. **8** is a diagram showing the circuit configuration of a radio-frequency power amplifier using an HBT, disclosed in Patent Document 1. The radio-frequency power amplifier of FIG. **8** includes an amplifying transistor Tr**1** and a bias circuit.

The amplifying transistor Tr**1** power-amplifies a radio-frequency signal inputted from an input terminal Pin and outputs the power-amplified radio-frequency signal from an output terminal Pout. The collector terminal of the amplifying transistor Tr**1** is connected to a power supply Vcc, and the emitter terminal is connected to ground potential.

The bias circuit, which supplies a bias current to the base terminal of the amplifying transistor Tr**1**, includes an emitter-follower transistor Tr**2**, a transistor Tr**8**, a resistance element R**1**, a resistance element R**13**, a resistance element R**14**, a capacitor C**1**, and a temperature compensation circuit **15**. The collector terminal of the emitter-follower transistor Tr**2**, which is an emitter follower, is connected to a power supply Vdc, and the base terminal is connected to the temperature compensation circuit **15**, surrounded by a dashed line, to one end of the resistance element R**13**, and to one end of the capacitor C**1**. The other end of the resistance element R**13** is connected to a reference power supply Vref, and the other end of the capacitor C**1** is connected to ground potential. The emitter terminal of the emitter-follower transistor Tr**2** is connected to the base terminal of the amplifying transistor Tr**1** via the resistance element R**1** and also connected to the collector terminal of the transistor Tr**8**. The collector terminal and base terminal of the transistor Tr**8** are connected to each other via the resistance element R**14**. The emitter terminal of the transistor Tr**8** is connected to ground potential.

The temperature compensation circuit **15** includes a transistor Tr**9**, a transistor Tr**10**, and a resistance element R**15**. The collector terminal of the transistor Tr**9** is connected to a power supply Vdc, and the base terminal is connected to the base terminal of the emitter-follower transistor Tr**2** and the collector terminal of the transistor Tr**10**. The emitter terminal of the transistor Tr**9** is connected to the base terminal of the transistor Tr**10** and connected to ground potential via the resistance element R**15**. The emitter terminal of the transistor Tr**10** is connected to ground potential.

The operating principle of the temperature compensation circuit **15** will be described. At low temperature, the diffusion potential between the base and emitter of the transistor Tr**9** rises. When the diffusion potential rises, the current (hereinafter referred to as "collector current") between the collector and emitter of the transistor Tr**9** decreases, and therefore the potential of the terminal, connected to the emitter terminal of the transistor Tr**9**, of the resistance element R**15** falls and the base potential of the transistor Tr**10** also falls. When the base potential of the transistor Tr**10** falls, the collector current of the transistor Tr**10** decreases, and therefore the current flowing through the resistance element R**13** decreases. When the current flowing through the resistance element R**13** decreases, the potential difference, i.e., the voltage, caused in the resistance element R**13** decreases, and therefore the base potential of the emitter-follower transistor Tr**2** rises. When the base potential rises, the collector current of the emitter-follower transistor Tr**2** increases, and therefore the base potential of the amplifying transistor Tr**1** rises. This compensates for the idle current of the amplifying transistor Tr**1** so that the value of the idle current increases. In contrast, at high temperature, the reverse operation to that performed at low temperature is performed. In this case, the base potential of the emitter-follower transistor Tr**2** falls, and therefore the idle current of the amplifying transistor Tr**1** is compensated for so that the value of the idle current decreases.

Here, there may be a case where a portion of the power of the transmitted signal from the amplifying transistor Tr**1** leaks to the bias circuit via the emitter-follower transistor Tr**2**. As a result, the base potential of the emitter-follower transistor Tr**2** may become so unstable that it is impossible to supply a stable bias current.

In the configuration of FIG. **8**, to solve this problem, the capacitor C**1** is connected to the base terminal of the emitter-follower transistor Tr**2**. However, in such a system as GSM (Global System for Mobile Communications) that uses a large transmitted signal, it is necessary to use the capacitor C**1** that has a considerably large capacitance, which significantly increases the size of the capacitor C**1**. On the other hand, in view of the miniaturization of the mobile phone, there are limitations to increasing the size of the capacitor C**1**. Therefore, with the configuration of FIG. **8**, it is difficult to supply a stable bias current.

In response, a radio-frequency power amplifier disclosed in Patent Document 2 is proposed. FIG. **9** is a diagram showing the circuit configuration of the radio-frequency power amplifier disclosed in Patent Document 2. The radio-frequency power amplifier of FIG. **9** includes an amplifying transistor Tr**1** and a bias circuit. Note that, in FIG. **9**, the same components as those of FIG. **8** will be denoted by the same numerals and will not be described.

The bias circuit, which supplies a bias current to the base terminal of the amplifying transistor Tr**1**, includes an emitter-follower transistor Tr**2**, resistance elements R**1**, R**2** and R**3**, and a temperature compensation circuit **11**. The base terminal of the emitter-follower transistor Tr**2** is connected to the temperature compensation circuit **11**, surrounded by a dashed line, and to one end of the resistance element R**2**. The other end of the resistance element R**2** is connected to a reference power supply Vref. The emitter terminal of the emitter-follower transistor Tr**2** is connected to the base terminal of the amplifying transistor Tr**1** via the resistance element R**1** and also connected to one end of the resistance element R**3**. The other end of the resistance element R**3** is connected to ground potential.

The temperature compensation circuit **11** includes a diode transistor Tr**3**, the base terminal and collector terminal of which are short-circuited and a diode transistor Tr**4**, the base terminal and collector terminal of which are short-circuited. The diode transistors Tr**3** and Tr**4** are connected to each other as two stages in cascade. The emitter terminal of the diode transistor Tr**4**, which is the lower stage, is connected to ground potential, and the collector terminal of the diode transistor Tr**3**, which is the upper stage, is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to the reference power supply Vref via the resistance element R**2**.

The operating principle of the temperature compensation circuit **11** will be described. The diffusion potential between the base of the diode transistor Tr**3** and the emitter of the diode transistor Tr**4** changes with temperature change, whereby the collector potential of the diode transistor Tr**3** (i.e., the base potential of the emitter-follower transistor Tr**2**) also changes with temperature change. Specifically, at low temperature, the diffusion potential between the base and emitter of the diode transistor Tr**3** rises. When the diffusion potential rises, the collector current of the diode transistor Tr**3** decreases, and therefore the current flowing through the resistance element R**2** decreases. When the current flowing through the resistance element R**2** decreases, the voltage caused in the resistance element R**2** decreases, and therefore the base potential of the emitter-follower transistor Tr**2** rises. When the base potential rises, the collector current of the emitter-follower transistor Tr**2** increases, and therefore the base potential of the amplifying transistor Tr**1** rises. This compensates for the idle current of the amplifying transistor Tr**1** so that the value of the idle current increases. In contrast, at high temperature, the reverse operation to that performed at low temperature is performed. In this case, the base potential of the emitter-follower transistor Tr**2** falls, and therefore the idle current of the amplifying transistor Tr**1** is compensated for so that the value of the idle current decreases.

The use of the temperature compensation circuit **11** described above suppresses the leakage power of the transmitted signal from the amplifying transistor Tr**1**, due to the parasitic capacitance between the base of the diode transistor Tr**3** and the emitter of the diode transistor Tr**4**. Therefore, with the configuration of FIG. **9**, it is possible, unlike the configuration of FIG. **8**, to smooth the base potential of the emitter-follower transistor Tr**2** without using a large-size capacitor C**1** besides the temperature compensation circuit, and therefore to supply a stable bias current.

Patent Document 1: Japanese Laid-Open Patent Publication No. 2005-101733

Patent Document 2: Japanese Laid-Open Patent Publication No. 2001-274636

However, with the radio-frequency power amplifier of FIG. **9**, it is impossible to sufficiently suppress the temperature dependence of the idle current of the amplifying transistor Tr**1**, due to the circuit configuration of the temperature compensation circuit **11**, and therefore it is impossible to sufficiently compensate for temperature.

To sufficiently compensate for temperature in the radio-frequency power amplifier of FIG. **9**, it is necessary to make the voltage value of the reference power supply Vref far greater than twice the diffusion potential between the base of the transistor Tr**3** and the emitter of the transistor Tr**4**. Additionally, to prevent the idle current of the amplifying transistor Tr**1** from significantly increasing, it is also necessary to increase the resistance value of the resistance element R**2**. However, when the resistance value of the resistance element R**2** is increased, the voltage caused in the resistance element R**2** increases when the operating current of the amplifying transistor Tr**1** increases due to a large signal. As a result, the power gain falls, which hinders high efficiency. Consequently, with the radio-frequency power amplifier of FIG. **9**, there are limitations to increasing the resistance value of the resistance element R**2**, and therefore it is difficult to sufficiently compensate for temperature.

SUMMARY OF THE INVENTION

Therefore, to solve the above problem, an object of the present invention is to provide a radio-frequency power amplifier having a bias circuit capable of making the temperature dependence, of the idle current of an amplifying transistor, lower than is conventionally the case and thus sufficiently compensating for temperature.

The present invention is directed to solving the above problem. A radio-frequency power amplifier according to the present invention includes: a first transistor operable to amplify a power of a radio-frequency signal; and a bias circuit operable to supply a bias current to the first transistor. The bias circuit includes: a second transistor that has a collector terminal connected to a first power supply; a first resistance element that has one end connected to an emitter terminal of the second transistor and has the other end connected to a base terminal of the first transistor; a second resistance element that has one end connected to the emitter terminal of the second transistor and has the other end connected to ground potential; at least one third resistance element provided between a base terminal of the second transistor and a second power supply; and a plurality of temperature compensation circuits connected to the base terminal of the second transistor which are operable to control a base potential of the second transistor so that the potential falls as a temperature rises.

Note that, in an embodiment described below, for example, the first transistor corresponds to an amplifying transistor Tr**1**, the first power supply corresponds to a power supply Vdc, the second transistor corresponds to an emitter-follower transistor Tr**2**, the first resistance element corresponds to a resistance element R**1**, the second resistance element corresponds to a resistance element R**3**, the second power supply corresponds to a reference power supply Vref, and the third resistance element corresponds to a resistance element R**2**.

Based on the configuration described above, the bias circuit includes the plurality of temperature compensation circuits. This makes it possible to make the temperature dependence, of the idle current of the first transistor, lower than is conventionally the case. As a result, based on the present embodiment, it is possible to provide a radio-frequency power amplifier having a bias circuit capable of sufficiently compensating for temperature.

It is preferable that the bias circuit may include a first temperature compensation circuit and a second temperature compensation circuit, that the first temperature compensation circuit may include: a third transistor that has a collector terminal and a base terminal that are short-circuited, the collector terminal being connected to the base terminal of the second transistor; and a fourth transistor that has a collector terminal and a base terminal that are short-circuited, the collector terminal being connected to an emitter terminal of the third transistor, and has an emitter terminal connected to ground potential, and that the second temperature compensation circuit may include: a first voltage divider circuit having a plurality of series resistance elements connected in series; a fifth transistor that has a collector terminal connected to the base terminal of the second transistor and an emitter terminal connected to ground potential; and a fourth resistance element that has one end connected to a connecting point of any of the series resistance elements of the first voltage divider circuit and has the other end connected to a base terminal of the fifth transistor.

Note that, in an embodiment described below, for example, the first temperature compensation circuit corresponds to a temperature compensation circuit **11**, the second temperature compensation circuit corresponds to a temperature compensation circuit **12**, a third transistor corresponds to a diode transistor Tr**3**, the fourth transistor corresponds to a diode transistor Tr**4**, the series resistance elements correspond to a resistance element R**4** and a resistance element R**5**, the fifth transistor corresponds to a transistor Tr**5**, and the fourth resistance element corresponds to a resistance element R**6**.

In this case, the bias circuit may further include at least one sixth resistance element provided between the base terminal of the second transistor and a connecting point of the third resistance element and the collector terminal of the fifth transistor. Note that, in the embodiments described below, for example, the sixth resistance element corresponds to a resistance element R**12**.

The bias circuit may further include a third temperature compensation circuit, and the third temperature compensation circuit may include: a second voltage divider circuit having a plurality of series resistance elements connected in series; a sixth transistor that has a collector terminal connected to the base terminal of the second transistor and has an emitter terminal connected to ground potential; and a fifth resistance element that has one end connected to a connecting point of any of the series resistance elements of the second voltage divider circuit and has the other end connected to a base terminal of the sixth transistor, and resistance values of the series resistance elements of the first voltage divider circuit, the series resistance elements of the second voltage divider circuit, the fourth resistance element, and the fifth resistance element may be each set so that an idle current of the first transistor decreases as a temperature rises at temperatures above a predetermined temperature.

Note that, in an embodiment described below, the third temperature compensation circuit corresponds to a temperature compensation circuit **14**, the series resistance element correspond to a resistance element R**9** and a resistance element R**10**, the sixth transistor corresponds to a transistor Tr**7**, and the fifth resistance element corresponds to a resistance element R**11**.

It is preferable that all of the series resistance elements may be arranged in the same direction on a substrate.

It is preferable that a mode switching circuit, connected to the base terminal of the second transistor, operable to switch a bias current to be supplied to the second transistor to a predetermined value of the bias current may be further included. In this case, the mode switching circuit may include: a power supply circuit operable to control an output of a predetermined voltage to start or stop; a seventh transistor that has an emitter terminal connected to ground potential; a seventh resistance element that has one end connected to an output of the power supply circuit and has the other end connected to a base terminal of the seventh transistor; and an eighth resistance element that has one end connected to a collector terminal of the seventh transistor and has the other end connected to the base terminal of the second transistor.

Note that, in an embodiment described below, for example, the seventh transistor corresponds to a transistor Tr**6**, the seventh resistance element corresponds to a resistance element R**7**, and the eighth resistance element corresponds to a resistance element R**8**.

Based on the present invention, it is possible to provide a radio-frequency power amplifier having a bias circuit capable of making the temperature dependence, of the idle current of an amplifying transistor, lower than is conventionally the case and thus sufficiently compensating for temperature.

These and other objects, features, aspects and advantages of the present invention will become more apparent from the following detailed description of the present invention when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a diagram showing the circuit configuration of a radio-frequency power amplifier according to a first embodiment;

FIG. **2** is a diagram showing an example of specific circuit configurations of a temperature compensation circuit **11** and a temperature compensation circuit **12**;

FIG. **3** is a diagram showing the temperature characteristics of the collector current of a transistor Tr**5** of the temperature compensation circuit **12**;

FIG. **4**A is a diagram showing the temperature characteristics of the idle current of an amplifying transistor Tr**1** of a conventional radio-frequency power amplifier, shown in FIG. **9**;

FIG. **4**B is a diagram showing the temperature characteristics of the idle current of an amplifying transistor Tr**1** of the radio-frequency power amplifier of the present invention, shown in FIG. **2**;

FIG. **5** is a diagram showing the circuit configuration of a radio-frequency power amplifier according to a second embodiment;

FIG. **6** is a diagram showing the circuit configuration of a radio-frequency power amplifier according to a third embodiment;

FIG. **7** is a diagram showing the circuit configuration of a radio-frequency power amplifier according to a fourth embodiment;

FIG. **8** is a diagram showing the circuit configuration of a radio-frequency power amplifier disclosed in Patent Document 1; and

FIG. **9** is a diagram showing the circuit configuration of a radio-frequency power amplifier disclosed in Patent Document 2.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to the drawings, embodiments of a radio-frequency power amplifier of the present invention will be described below.

First Embodiment

With reference to FIG. **1**, the circuit configuration of a radio-frequency power amplifier according to a first embodiment of the present invention will be described. FIG. **1** is a diagram showing the circuit configuration of the radio-frequency power amplifier according to the first embodiment. The radio-frequency power amplifier of FIG. **1** includes an amplifying transistor Tr**1** and a bias circuit. Note that, in FIG. **1**, the same components as those of FIG. **9** will be denoted by the same numerals and therefore will not be described in detail.

The bias circuit, which supplies a bias current to the base terminal of the amplifying transistor Tr**1**, includes an emitter-follower transistor Tr**2**, resistance elements R**1**, R**2** and R**3**, a temperature compensation circuit **11**, and a temperature compensation circuit **12**.

The temperature compensation circuit **11**, which is connected to the base terminal of the emitter-follower transistor Tr**2**, compensates for the idle current of the amplifying transistor Tr**1** in response to a temperature change by controlling the base potential of the emitter-follower transistor Tr**2** so that the potential falls as the temperature rises.

The temperature compensation circuit **12**, which is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to a reference power supply Vref, compensates for the idle current of the amplifying transistor Tr**1** in response to a temperature change by controlling the base potential of the emitter-follower transistor Tr**2** so that the potential falls as the temperature rises.

Next, specific circuit configurations of the temperature compensation circuits **11** and **12** will be described. FIG. **2** is a diagram showing an example of the specific circuit configurations of the temperature compensation circuits **11** and **12**. The temperature compensation circuit **11**, which is similar in configuration to the temperature compensation circuit **11** of FIG. **9**, includes a diode transistor Tr**3**, the base terminal and collector terminal of which are short-circuited and a diode transistor Tr**4**, the base terminal and collector terminal of which are short-circuited. The diode transistors Tr**3** and Tr**4** are connected to each other as two stages in cascade. The emitter terminal of the diode transistor Tr**4**, which is the lower stage, is connected to ground potential. The collector terminal of the diode transistor Tr**3**, which is the upper stage, is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to the reference power supply Vref via the resistance element R**2**.

The temperature compensation circuit **12** includes a transistor Tr**5** and resistance elements R**4**, R**5** and R**6**. The resistance elements R**4** and R**5** are connected to each other as two stages in cascade. The terminal, of the resistance element R**4**, not connected to the resistance element R**5** is connected to the reference power supply Vref, and the terminal, of the resistance element R**5**, not connected to the resistance element R**4** is connected to ground potential. Thus, the resistance elements R**4** and R**5** form a voltage divider circuit. The connecting point of the resistance elements R**4** and R**5** is connected to the base terminal of the transistor Tr**5** via the resistance element R**6**. The emitter terminal of the transistor Tr**5** is connected to ground potential. The collector terminal of the transistor Tr**5** is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to the reference power supply Vref via the resistance element R**2**.

The operating principle of the temperature compensation circuit **11** is similar to that of the temperature compensation circuit **11** of FIG. **9**, and therefore will not be described. The operating principle of the temperature compensation circuit **12** will be described below. FIG. **3** is a diagram showing the temperature characteristics of the collector current of the transistor Tr**5** of the temperature compensation circuit **12**. The resistance values of the resistance elements R**4** and R**5** are set so that the collector current flows through the transistor Tr**5** even at the lowest temperature of the temperature conditions under which the radio-frequency power amplifier is used. The resistance value of the resistance element R**6** is set so that the slope of the temperature characteristics of the collector current of the transistor Tr**5** is an arbitrary slope. These settings of the resistance elements R**4**, R**5**, and R**6** increase the collector current of the transistor Tr**5** as the temperature rises from low to high, as shown in FIG. **3**. Here, the collector terminal of the transistor Tr**5** is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to the reference power supply Vref via the resistance element R**2**. Since the collector current of the transistor Tr**5** increases at high temperature as shown in FIG. **3**, the voltage caused in the resistance element R**2** increases further, and therefore the base potential of the emitter-follower transistor Tr**2** falls further. At high temperature, this compensates for the idle current of the amplifying transistor Tr**1** so that the value of the idle current decreases.

FIG. **4**A is a diagram showing the temperature characteristics of the idle current of the amplifying transistor Tr**1** of the conventional radio-frequency power amplifier, shown in FIG. **9**. The temperature characteristics of FIG. **4**A indicate the characteristics when the value of each component of the bias circuit is set so that the idle current of the amplifying transistor Tr**1** is 100 mA at an environmental temperature of 25° C., and also, the voltage value of the reference power supply Vref is set to 2.8 V, which is a control voltage used for a general mobile phone. Referring to FIG. **4**A, m**11** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of −25° C., m**12** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of 25° C., and m**13** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of 75° C. As shown in FIG. **4**A, since m**11** is 66 mA and m**13** is 126 mA, it is understood that the change of the current is approximately twofold at a temperature difference of 100° C. The reason is that the current consumed in the temperature compensation circuit **11** of FIG. **9** does not sufficiently increase as the temperature rises from low to high when the voltage value of the reference power supply Vref is set to 2.8 V.

FIG. **4**B is a diagram showing the temperature characteristics of the idle current of the amplifying transistor Tr**1** of the radio-frequency power amplifier of the present invention, shown in FIG. **2**. Similarly to FIG. **4**A, the temperature characteristics of FIG. **4**B indicate the characteristics when the value of each component of the bias circuit is set so that the idle current of the amplifying transistor Tr**1** is 100 mA at an environmental temperature of 25° C., and also, the voltage value of the reference power supply Vref is set to 2.8 V, which is a control voltage used for a general mobile phone. Referring to FIG. **4**B, m**21** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of −25° C., m**22** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of 25° C., and m**23** represents the idle current of the amplifying transistor Tr**1** at an environmental temperature of 75° C. As shown in FIG. **4**B, since m**21** is 100 mA and m**23** is 102 mA, it is understood that the change of the current at a temperature difference of 100° C. is suppressed to approximately 2 mA.

As described above, in the present embodiment, the bias circuit includes two temperature compensation circuits (the temperature compensation circuits **11** and **12**). This makes it possible to make the temperature dependence, of the idle current of the amplifying transistor Tr**1**, lower than is conventionally the case. As a result, based on the present embodiment, it is possible to provide a radio-frequency power amplifier having a bias circuit capable of sufficiently compensating for temperature.

Further, the present embodiment includes the temperature compensation circuit **11**, which is similar to that of FIG. **9**. This makes it possible, unlike the configuration of FIG. **8**, to smooth the base potential of the emitter-follower transistor Tr**2** without using a large-size capacitor C**1** besides the temperature compensation circuit, and therefore to supply a stable bias current.

Furthermore, in the conventional temperature compensation circuit **15** of FIG. **8**, since the transistors Tr**9** and Tr**10** form a current loop, noise may deteriorate and an oscillation may occur in the bias circuit. In the present embodiment, however, as shown in FIG. **2**, the temperature compensation circuits **11** and **12** do not form a current loop. Thus, in the present embodiment, noise does not deteriorate nor does an oscillation occur in the bias circuit due to a current loop.

Note that the temperature compensation circuits **11** and **12** may not necessarily have the circuit configurations shown in FIG. **2**, and may have other circuit configurations.

Note that the formation directions, on a substrate, of the resistance elements R**4** and R**5** of the temperature compensation circuit **12** are not particularly described above, but it is preferable that the formation directions of the resistance elements R**4** and R**5** be the same. A formation direction refers to the direction from one terminal of each resistance to the other. The same formation direction makes it possible to suppress production variations of the resistance values of the resistance elements R**4** and R**5**, and therefore to obtain a desired potential at the connecting point of the resistance elements R**4** and R**5** with high accuracy. Note that, in the temperature compensation circuit **12**, the voltage divider circuit is formed using two resistance elements (the resistance elements R**4** and R**5**), but the voltage divider circuit may be formed by connecting three or more resistance elements in series.

Second Embodiment

With reference to FIG. **5**, the circuit configuration of a radio-frequency power amplifier according to a second embodiment of the present invention will be described. FIG. **5** is a diagram showing the circuit configuration of the radio-frequency power amplifier according to the second embodiment. The radio-frequency power amplifier of FIG. **5** is different from the radio-frequency power amplifier of FIG. **2** in that the radio-frequency power amplifier of FIG. **5** further includes a mode switching circuit **13**. The other components of the circuit configuration of FIG. **5** are the same as those of the circuit configuration of FIG. **2**, and therefore will be denoted by the same numerals and will not be described.

The mode switching circuit **13** includes a power supply circuit **131**, a resistance element R**7**, a resistance element R**8**, and a transistor Tr**6**. The base terminal of the transistor Tr**6** is connected to the output of the power supply circuit **131** via the resistance element R**7**. The collector terminal of the transistor Tr**6** is connected to the base terminal of the emitter-follower transistor Tr**2** via the resistance element R**8** and also connected to the reference power supply Vref via the resistance elements R**8** and R**2**. The emitter terminal of the transistor Tr**6** is connected to ground potential. In accordance with a rule set in advance, the power supply circuit **131** controls the output of a mode switching voltage Vmod to start (i.e., the output is turned ON) or stop (i.e., the output is turned OFF).

The operating principle of the mode switching circuit **13** will be described. The output of the mode switching voltage Vmod is turned ON or OFF in accordance with a rule set in advance in the power supply circuit **131**, whereby the transistor Tr**6** operates as a switch (SW). When the output of the mode switching voltage Vmod is turned ON, the transistor Tr**6** is turned ON, and therefore the collector current of the transistor Tr**6** flows. When the collector current of the transistor Tr**6** flows, the base potential of the emitter-follower transistor Tr**2** falls, and therefore the collector current of the emitter-follower transistor Tr**2** decreases. When the collector current decreases, the base potential of the amplifying transistor Tr**1** falls, and therefore the idle current of the amplifying transistor Tr**1** is suppressed so that the value of the idle current decreases.

As described above, in the present embodiment, the bias circuit includes the mode switching circuit **13**. Here, it is assumed, for example, that the rule is set in the power supply circuit **131** so that, in the case where the dynamic range of the output power of the radio-frequency power amplifier is wide, the output of the mode switching voltage Vmod is turned ON at the time of a low output. In this case, it is possible to suppress the idle current of the amplifying transistor Tr**1** at the time of a low output, and therefore to improve the power added efficiency of the radio-frequency power amplifier.

Note that the mode switching circuit **13** described above may not necessarily have the circuit configuration shown in FIG. **5**, and may have another circuit configuration.

Third Embodiment

With reference to FIG. **6**, the circuit configuration of a radio-frequency power amplifier according to a third embodiment of the present invention will be described. FIG. **6** is a diagram showing the circuit configuration of the radio-frequency power amplifier according to the third embodiment. The radio-frequency power amplifier of FIG. **6** is different from the radio-frequency power amplifier of FIG. **2** in that the radio-frequency power amplifier of FIG. **6** further includes a temperature compensation circuit **14**. The other components of the circuit configuration of FIG. **6** are the same as those of the circuit configuration of FIG. **2**, and therefore will be denoted by the same numerals and will not be described.

The temperature compensation circuit **14**, which is similar in configuration to the temperature compensation circuit **12**, is connected to the base terminal of the emitter-follower transistor Tr**2** and thus the temperature compensation circuit **14**, as well as the temperature compensation circuits **11** and **12**, further compensates for temperature. More specifically, the temperature compensation circuit **14** includes a transistor Tr**7** and resistance elements R**9**, R**10** and R**11**. The resistance elements R**9** and R**10** are connected to each other as two stages in cascade. The terminal, of the resistance element R**9**, not connected to the resistance element R**10** is connected to the reference power supply Vref, and the terminal, of the resistance element R**10**, not connected to the resistance element R**9** is connected to ground potential. Thus, the resistance elements R**9** and R**10** form a voltage divider circuit. The connecting point of the resistance elements R**9** and R**10** is connected to the base terminal of the transistor Tr**7** via the resistance element R**11**. The emitter terminal of the transistor Tr**7** is connected to ground potential. The collector terminal of the transistor Tr**7** is connected to the base terminal of the emitter-follower transistor Tr**2** and also connected to the reference power supply Vref via the resistance element R**2**. Note that the operating principle of the temperature compensation circuit **14** is similar to that of the temperature compensation circuit **12**, and therefore will not be described.

Here, the resistance values of the resistance elements R**4**, R**5**, and R**6** of the temperature compensation circuit **12** and the resistance values of the resistance elements R**9**, R**10**, and R**11** of the temperature compensation circuit **14** are set to different values from each other, whereby the temperature characteristics of the idle current of the amplifying transistor Tr**1** can have an inflection point. Consequently, the temperature characteristics of the idle current of the amplifying transistor Tr**1** may have such an inflection point that, for example, the idle current decreases only as the temperature rises at temperatures above a desired temperature. Due to this inflection point, the idle current of the amplifying transistor Tr**1** decreases at high temperature even when the idle current is high at low temperature, and therefore it is possible to suppress thermal runaway of the idle current of the amplifying transistor Tr**1** at high temperature.

Note that the circuit configuration of the temperature compensation circuit **14** may not necessarily be the same as that of the temperature compensation circuit **12** as described above, and the temperature compensation circuit **14** may have another circuit configuration. Additionally, in the present embodiment, the mode switching circuit **13** of the second embodiment may be further provided.

Fourth Embodiment

With reference to FIG. **7**, the circuit configuration of a radio-frequency power amplifier according to a fourth embodiment of the present invention will be described. FIG. **7** is a diagram showing the circuit configuration of the radio-frequency power amplifier according to the fourth embodiment. The radio-frequency power amplifier of FIG. **7** is different from the radio-frequency power amplifier of FIG. **2** in that the radio-frequency power amplifier of FIG. **7** further includes a resistance element R**12**. The other components of the circuit configuration of FIG. **7** are the same as those of the circuit configuration of FIG. **2**, and therefore will be denoted by the same numerals and will not be described.

The resistance element R**12** is provided between the resistance element R**2** and the connecting point of the base terminal of the emitter-follower transistor Tr**2** and the collector terminal of the diode transistor Tr**3**.

Here, the use of the amplifying transistor Tr**1** that has a small emitter area decreases the bias current flowing between the base and emitter of the amplifying transistor Tr**1**, compared to the use of the amplifying transistor Tr**1** that has a large emitter area, and therefore the base-emitter current of the emitter-follower transistor Tr**2** decreases.

In the configuration shown in FIG. **2**, only the resistance element R**2** is provided between the reference power supply Vref and the base terminal of the emitter-follower transistor Tr**2**. As a result, the use of the amplifying transistor Tr**1** that has a small emitter area decreases the voltage caused in the resistance element R**2** and raises the base potential of the emitter-follower transistor Tr**2**. To suppress this rise, it is necessary to increase the resistance value of the resistance element R**2**. However, since the collector current of the transistor Tr**5** of the temperature compensation circuit **12** significantly increases at high temperature, if the resistance value of the resistance element R**2** is increased, the base potential of the emitter-follower transistor Tr**2** may significantly fall, and therefore the amplifying transistor Tr**1** may be turned OFF at high temperature. To prevent this, it may be possible to decrease the collector current of the transistor Tr**5** by increasing the resistance value of the resistance element R**6** of the temperature compensation circuit **12**, but it is necessary to increase the area of the resistance element R**6**.

In contrast, in the configuration of the present embodiment, shown in FIG. **7**, the resistance elements R**2** and R**12** are provided between the reference power supply Vref and the base terminal of the emitter-follower transistor Tr**2**. Additionally, the collector current of the transistor Tr**5** of the temperature compensation circuit **12** does not flow through the resistance element R**12**. That is, in the configuration of the present embodiment, the resistance value between the reference power supply Vref and the base terminal of the emitter-follower transistor Tr**2** is increased using the resistance element R**12** that is not involved in the collector current of the transistor Tr**5** of the temperature compensation circuit **12**. Consequently, the configuration of the present embodiment can suppress the rise of the base potential of the emitter-follower transistor Tr**2** without increasing the resistance value of the resistance element R**2**. Further, since the resistance value of the resistance element R**2** is not increased, the base potential of the emitter-follower transistor Tr**2** does not significantly rise at high temperature even when the collector current of the transistor Tr**5** of the temperature compensation circuit **12** increases at high temperature. Therefore, it is possible to prevent the amplifying transistor Tr**1** from being turned OFF at high temperature.

As described above, in the present embodiment, the resistance elements R**2** and R**12** are provided between the reference power supply Vref and the base terminal of the emitter-follower transistor Tr**2**. Consequently, in the configuration of the present embodiment, the use of the amplifying transistor Tr**1** that has a small emitter area makes it possible to suppress the rise of the base potential of the emitter-follower transistor Tr**2** without increasing the size of the resistance element R**2**, and also possible to prevent the amplifying transistor Tr**1** from being turned OFF at high temperature without increasing the area of the resistance element R**6**.

Note that, in FIG. **7**, the reference power supply Vref is connected to the resistance elements R**2** and R**12** that are connected to each other in series, but may be connected to three or more series resistance elements connected in series. In this case, the collector terminal of the transistor Tr**5** of the temperature compensation circuit **12** may be connected to the reference power supply Vref via one or more series resistance elements and also connected to the base terminal of the emitter-follower transistor Tr**2** via one or more series resistance elements. Alternatively, when a plurality of temperature compensation circuits **12** are provided, the collector terminals of the transistors Tr**5** of the temperature compensation circuits **12** may be connected to the same connecting point or different connecting points between series resistance elements.

Note that, in the present embodiment, the mode switching circuit **13** of the second embodiment may be further provided. In this case, the collector terminal of the transistor Tr**6** of the mode switching circuit **13** may be connected to the reference power supply Vref via the resistance element R**8** and one or more series resistance elements and also connected to the base terminal of the emitter-follower transistor Tr**2** via the resistance element R**8** and one or more series resistance elements.

While the invention has been described in detail, the foregoing description is in all aspects illustrative and not restrictive. It is understood that numerous other modifications and variations can be devised without departing from the scope of the invention.

What is claimed is:

1. A radio-frequency power amplifier comprising:

a first transistor operable to amplify a power of a radio-frequency signal; and

a bias circuit operable to supply a bias current to the first transistor;

the bias circuit including:

a second transistor that has a collector terminal connected to a first power supply;

a first resistance element that has one end connected to an emitter terminal of the second transistor and has the other end connected to a base terminal of the first transistor;

a second resistance element that has one end connected to the emitter terminal of the second transistor and has the other end connected to ground potential;

at least one third resistance element provided between a base terminal of the second transistor and a second power supply; and

a plurality of temperature compensation circuits connected to the base terminal of the second transistor and operable to control a base potential of the second transistor so that the potential falls as a temperature rises, at least one of the plurality of temperature compensation circuits being unlike all the rest of the plurality of temperature compensation circuits in configuration.

2. The radio-frequency power amplifier according to claim **1**,

wherein the bias circuit includes a first temperature compensation circuit and a second temperature compensation circuit,

wherein the first temperature compensation circuit includes:

a third transistor that has a collector terminal and a base terminal that are short-circuited, the collector terminal being connected to the base terminal of the second transistor; and

a fourth transistor that has a collector terminal and a base terminal that are short-circuited, the collector terminal being connected to an emitter terminal of the third transistor, and has an emitter terminal connected to ground potential, and

wherein the second temperature compensation circuit includes:

a first voltage divider circuit having a plurality of series resistance elements connected in series;

a fifth transistor that has a collector terminal connected to the base terminal of the second transistor and an emitter terminal connected to ground potential; and

a fourth resistance element that has one end connected to a connecting point of any of the series resistance elements of the first voltage divider circuit and has the other end connected to a base terminal of the fifth transistor.

3. The radio-frequency power amplifier according to claim **2**,

wherein the bias circuit further includes at least one sixth resistance element provided between the base terminal of the second transistor and a connecting point of the third resistance element and the collector terminal of the fifth transistor.

4. The radio-frequency power amplifier according to claim **2**,

wherein the bias circuit further includes a third temperature compensation circuit,

wherein the third temperature compensation circuit includes:

a second voltage divider circuit having a plurality of series resistance elements connected in series;

a sixth transistor that has a collector terminal connected to the base terminal of the second transistor and has an emitter terminal connected to ground potential; and

a fifth resistance element that has one end connected to a connecting point of any of the series resistance elements of the second voltage divider circuit and has the other end connected to a base terminal of the sixth transistor, and

wherein resistance values of the series resistance elements of the first voltage divider circuit, the series resistance elements of the second voltage divider circuit, the fourth resistance element, and the fifth resistance element are each set so that an idle current of the first transistor decreases as a temperature rises at temperatures above a predetermined temperature.

5. The radio-frequency power amplifier according to any one of claims **2** through **4**,

wherein all of the series resistance elements are arranged in the same direction on a substrate.

6. The radio-frequency power amplifier according to claim **1**, further comprising:

a mode switching circuit, connected to the base terminal of the second transistor, operable to switch a bias current to be supplied to the second transistor to a predetermined value of the bias current.

7. The radio-frequency power amplifier according to claim **6**,

wherein the mode switching circuit includes:

a power supply circuit operable to control an output of a predetermined voltage to start or stop;

a seventh transistor that has an emitter terminal connected to ground potential;

a seventh resistance element that has one end connected to an output of the power supply circuit and has the other end connected to a base terminal of the seventh transistor; and

an eighth resistance element that has one end connected to a collector terminal of the seventh transistor and has the other end connected to the base terminal of the second transistor.

(57) **ABSTRACT**

An RF power amplifier includes a push-pull amplifier having field effect transistors. Temperature compensating bias circuitry provides a temperature compensated bias voltage to the transistors for decreasing the bias voltage thereof as temperature increases. The temperature compensating bias circuitry includes a temperature sensor generating a temperature signal. A first amplifier provides a first temperature dependent voltage based on the temperature signal. A second amplifier provides a second temperature dependent voltage based on the temperature signal. The first and second temperature dependent voltages change at substantially the same rate in response to the temperature signal. A potentiometer receives the first and second temperature dependent voltages such that a voltage across the potentiometer remains substantially constant when the first and second temperature dependent voltages change. An output of the bias circuitry is connected to at least one of the transistors and supplies the temperature compensated bias voltage to the at least one of the transistors.

SOLID-STATE RF POWER AMPLIFIER FOR RADIO TRANSMITTERS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. patent application Ser. No. 11/749,786, filed on May 17, 2007, which claims the benefit of U.S. Provisional Patent Application Ser. No. 60/801,006, filed May 17, 2006 and the benefit of U.S. Provisional Patent Application Ser. No. 60/747,662, filed May 18, 2006. The respective disclosures in the above-referenced applications are incorporated herein by reference in their entireties.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to power amplifiers, and more particularly to radio frequency (RF) power amplifiers employing high voltage and high power metal-oxide semiconductor field-effect transistors (MOSFET).

2. Description of Related Art

High-power RF amplifiers adapted to operate over a range of 1-60 MHz without tuning have typically employed vacuum tubes. It would be desirable to provide a high-power RF amplifier for operation over a range of 1-60 MHz, and which employs a minimum number of MOSFET transistors instead of vacuum tubes.

BRIEF SUMMARY OF THE INVENTION

In accordance with one aspect of the invention, provided is an RF power amplifier including a first field effect transistor having a first gate, a first source, and a first drain, having an output power rating of at least 200 watts, and operating with a drain-to-source voltage that is greater than 50 VDC. The amplifier includes a second field effect transistor having a second gate, a second source, and a second drain, having an output power rating of at least 200 watts, and operating with a drain-to-source voltage that is greater than 50 VDC. The transistors are configured as a push-pull amplifier. The amplifier further includes an RF signal input. An input transformer is connected to the RF signal input. The input transformer has respective balanced outputs connected to the first gate and the second gate. A broadband output transformer has a first balanced input connected to the first drain, and a second balanced input connected to the second drain. The broadband output transformer has an input to output impedance ratio of 1:4 and at least some flux cancellation occurs within the broadband output transformer. Temperature compensating bias circuitry provides a temperature compensated bias voltage to the first field effect transistor and the second field effect transistor for decreasing the bias voltage of the first field effect transistor and the second field effect transistor as transistor temperature increases, in order to maintain a constant bias current level over temperature. The temperature compensating bias circuitry includes a temperature sensor generating a temperature signal. A first amplifier has an output providing a first temperature dependent voltage based on the temperature signal. A second amplifier has an output providing a second temperature dependent voltage based on the temperature signal. The first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal. A potentiometer is connected to the output of the first amplifier and the output of the second amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage and the second temperature dependent voltage change. A bias output of the temperature compensating bias circuitry is connected to at least one of the first field effect transistor and the second field effect transistor and supplies the temperature compensated bias voltage to the at least one of the first field effect transistor and the second field effect transistor.

In accordance with another aspect of the invention, provided is an RF power amplifier including a first plurality of field effect transistors having directly interconnected drains and respective output power ratings of at least 100 watts, and a second plurality of field effect transistors having directly interconnected drains and respective output power ratings of at least 100 watts. The transistors operate with a drain-to-source voltage that is greater than 50 VDC. The first plurality of field effect transistors and the second plurality of field effect transistors together form a push-pull amplifier having an output power rating of at least 400 watts. The amplifier further includes an RF signal input. An input transformer is connected to the RF signal input. The input transformer has respective balanced outputs connected to the gates of the transistors. A broadband output transformer has a first balanced input connected to the drains of the first plurality of field effect transistors, and a second balanced input connected to the drains of the second plurality of field effect transistors. The broadband output transformer has an input to output impedance ratio of 1:4 and at least some flux cancellation occurs within the broadband output transformer. Temperature compensating bias circuitry provides a temperature compensated bias voltage to the first plurality of field effect transistors and the second plurality of field effect transistors for decreasing the bias voltage of the first plurality of field effect transistors and the second plurality of field effect transistors as transistor temperature increases, in order to maintain a constant bias current level over temperature. The temperature compensating bias circuitry includes a temperature sensor generating a temperature signal. A first amplifier has an output providing a first temperature dependent voltage based on the temperature signal. A second amplifier has an output providing a second temperature dependent voltage based on the temperature signal. The first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal. A potentiometer is connected to the output of the first amplifier and the output of the second amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage and the second temperature dependent voltage change. A bias output of the temperature compensating bias circuitry is connected to at least one of the first plurality of field effect transistors and the second plurality of field effect transistors and supplies the temperature compensated bias voltage to the at least one of the first plurality of field effect transistors and the second plurality of field effect transistors.

In accordance with another aspect of the invention, provided is an RF power amplifier including a push-pull amplifier, the push-pull amplifier comprising a first field effect transistor and a second field effect transistor. Temperature compensating bias circuitry provides a temperature compensated bias voltage to the first field effect transistor and the second field effect transistor for decreasing the bias voltage of the first field effect transistor and the second field effect transistor as transistor temperature increases. The temperature compensating bias circuitry includes a temperature sensor generating a temperature signal. A first amplifier has an output providing a first temperature dependent voltage based on the temperature signal. A potentiometer is connected to the output of the first amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage changes. A bias output of the temperature compensating bias circuitry is connected to at least one of the first field effect transistor and the second field effect transistor and supplies the temperature compensated bias voltage to the at least one of the first field effect transistor and the second field effect transistor.

In accordance with another aspect of the invention, provided is an RF power amplifier including a push-pull amplifier, the push-pull amplifier comprising a first field effect transistor having a first drain and a second field effect transistor having a second drain. A broadband output transformer has a first balanced input and a second balanced input. A first DC-blocking transformer is connected between the first balanced input and the first drain. A second DC-blocking transformer is connected between the second balanced input and the second drain.

In accordance with another aspect, provided is an RF power amplifier. The RF power amplifier includes a first amplifier module and a second amplifier module. The first amplifier module comprises a first push-pull amplifier including a plurality of field effect transistors and a first output balun transformer. An output impedance of the first amplifier module is 25 ohms. The second amplifier module comprises a second push-pull amplifier including a plurality of field effect transistors and a second output balun transformer. The output impedance of the second amplifier module is 25 ohms. A combiner is connected to the first amplifier module and the second amplifier module. The combiner comprises an unbalanced-to-unbalanced output transformer having an input-to-output impedance ratio of 1:4. The combiner combines an output from the first amplifier module and an output from the second amplifier module into a combined signal. The combined signal is supplied to the unbalanced-to-unbalanced output transformer. An output impedance of the combiner is 50 ohms.

FIG. **11** is a schematic circuit diagram of an RF power amplifier; and

FIG. **12** is a schematic circuit diagram of an RF power amplifier.

DETAILED DESCRIPTION OF THE INVENTION

As used herein, the terms “connected” and “connected to” refer a physical and/or electrical joining or linking of one thing to another, and includes direct and indirect connections. For example, an amplifier can be connected to an RF signal input by direct electrical connection between the amplifier and input, or connected to said input via an indirect electrical connection, such as through an interposing resistor or capacitor. In the former case, the amplifier is directly connected to the input. In the latter case, the amplifier is indirectly connected to the input. However, in both cases, the amplifier is connected to the RF input.

FIG. **1** shows a top level schematic block diagram of a modular RF power amplifier system. The amplifier system includes an RF input terminal **10** and an RF output terminal **11**. In an embodiment, the characteristic impedance of the input and output terminals is 50 ohms. The terminals **10**, **11** can be adapted for use with removable connectors. For example, the terminals **10**, **11** can include a BNC or SMA female connector for removably connecting to a BNC or SMA male connector, respectively.

An RF signal to be amplified by the amplifier system is provided at the RF input terminal **10**. The RF signal is split by splitter **12** into separate signals to be amplified by a number of power amplifier modules **13***a*-**13***d*. In the example of FIG. **1**, four power amplifier modules **13***a*-**13***d* are provided. Therefore, the splitter **12** splits the RF signal into four separate signals. It is to be appreciated that fewer than four power amplifier modules could be provided, such as two or three amplifier modules, for example. It is to be further appreciated that greater than four power amplifier modules could be provided, such as six or eight amplifier modules, for example. The splitter **12** is designed to split the RF input signal into as many separate signals as there are power amplifier modules. The splitter **12** can include a cascade of separate splitters for staged splitting of the RF input signal into a number of separate signals.

The power amplifier modules **13***a*-**13***d* amplify the separate signals from the splitter **12** according to the power ratings of the amplifier modules **13***a*-**13***d*. In an embodiment, each power amplifier module **13***a*-**13***d* has a power rating of 400 watts. A modular RF power amplifier system employing four 400 watt power amplifier modules would provide approximately 1600 watts of total amplification. In another embodiment, each power amplifier module **13***a*-**13***d* has a power rating of 600 watts. A modular RF power amplifier system employing four 600 watt power amplifiers would provide approximately 2400 watts of total amplification. In still another embodiment, each power amplifier module **13***a*-**13***d* has a power rating of 1200 watts. A modular RF power amplifier system employing four 1200 watt power amplifiers would provide approximately 4800 watts of total amplification. In still another embodiment, each power amplifier module **13***a*-**13***d* has a power rating of 1500 watts. A modular RF power amplifier system employing four 1500 watt power amplifies would provide approximately 6000 watts of total amplification. As discussed above, fewer than four power amplifier modules could be provided or greater than four power amplifier modules could be provided. The number of power amplifier modules to be used and their power ratings can be chosen based on the required power output.

Example power amplifier modules **13***a*-**13***d* are shown in FIGS. **2** and **3** and are discussed in detail below. In an embodiment, each power amplifier module **13***a*-**13***d* is provided on a separate printed circuit board. In other embodiments, a plurality of amplifier modules are provided on one or more printed circuit boards.

Outputs from each of the power amplifier modules **13***a*-**13***d* are provided to a combiner **14**. In the example of FIG. **1**, four power amplifier modules **13***a*-**13***d* are provided and the combiner **14** combines the four outputs from the amplifier modules into a single, combined RF output. The combiner **14** is designed to combine as many signals as there are power amplifier modules. The combiner **14** can include a cascade of separate combiners for staged combining of the amplified signals into a combined signal. As shown in FIG. **1**, the RF output from the combiner **14** is provided to the RF output terminal **11**.

An RF power amplifier could comprise a single amplifier module, rather than a plurality of modules **13***a*-**13***d* as shown in FIG. **1**. An RF power amplifier having a single amplifier module would not require the splitter **12** and combiner **14**.

FIG. **2** shows a push-pull power amplifier module **21**. Transistors Q**1** and Q**2** form a push-pull pair for amplifying an RF signal.

The components that form the amplifier module **21** can be mounted on a printed circuit board **22**. The amplifier module includes an RF input terminal **23** and an RF output terminal **24**. In an embodiment, the characteristic impedance of the module's input and output terminals is 50 ohms. The terminals **23**, **24** can be adapted for use with removable connectors, such as BNC or SMA connectors, for example.

An RF signal to be amplified by the amplifier module **21** is provided at the RF input terminal **23**. The RF signal is transmitted to an input transformer T**1**. The transformer T**1** has an unbalanced or single-ended side, which is connected to the RF input terminal **23**. The unbalanced or single-ended side is coupled to a balanced or differential side of the transformer T**1**. The transformer T**1** is shown as a so-called conventional transformer, having separated primary and secondary windings. It is to be appreciated that the transformer T**1** could be constructed as a transmission line transformer, which does not have separated primary and secondary windings. An optional ground reference is provided for the transformer's balanced or differential side via a resistor R**1**. The transformer T**1** has an input to output impedance ratio of 4:1, for example, and serves to divide the unbalanced RF signal into balanced signals, 180° out of phase, for amplification by the push-pull transistor pair Q**1**, Q**2**, and subsequent combination. It is to be appreciated that the transformer T**1** could have an input to output impedance ratio of other than 4:1, such as 1:1.414, 1:9, 1:25, 3:2, etc. Further, it is to be appreciated that a so-called pi attenuator or pi input attenuator (not shown) comprising a plurality of resistors in a Greek letter "pi" configuration could be provided between the RF input terminal **23** and the transformer T**1**, for normalizing gain of the amplifier module **21**. Other attenuators could be provided between the RF input terminal **23** and the transformer T**1**, such as an L attenuator or a T attenuator, for example.

The input transformer T**1** is shown as an unbalanced-to-balanced transformer. However, it is to be appreciated that T**1** could alternatively be a balanced-to-balanced transformer.

An optional compensation capacitor C**1** is connected across the balanced terminals of the transformer T**1** and provides a low-pass filter response which absorbs the inductance of T**1** and helps compensate for a loss of gain at higher frequencies.

The transistors Q**1**, Q**2** that form the push-pull pair are high-voltage MOSFET RF power transistors. The transistors Q**1**, Q**2** have output power ratings of at least 150 watts, preferably at least 200 watts, and operate with a drain-to-source voltage that is greater than 50 VDC, such as 62 VDC, 72 VDC, 86 VDC, 96 VDC or 100 VDC, for example. Example transistors Q**1**, Q**2** have output power ratings of 150 watts, 300 watts, and 750 watts. An example 150 watt transistor is model ARF520 manufactured by ADVANCED POWER TECHNOLOGY®. A further example 150 watt transistor is model SD3931 manufactured by STMICROELECTRONICS®. An example 300 watt transistor is model SD3933 manufactured by STMICROELECTRONICS®. An example 750 watt transistor is model ARF1500 manufactured by ADVANCED POWER TECHNOLOGY®. It is to be appreciated that transistors having output power ratings other than 150 watts, 300 watts, and 750 watts can be used in an amplifier module as shown in FIG. **2**. For example, 200 watt transistors can be used in the amplifier module.

An amplifier module **21** as shown in FIG. **2**, having 150 watt transistors Q**1**, Q**2** forming a push-pull pair, can have a power rating of 300 watts. An amplifier module **21** having 300 watt transistors Q**1**, Q**2** forming a push-pull pair, can have a power rating of 600 watts. An amplifier module **21** having 750 watt transistors Q**1**, Q**2** forming a push-pull pair, can have a power rating of 1500 watts. It is to be appreciated that the power rating of the amplifier module depends on the power rating of the selected transistors and the drain-to-source voltage at which the transistors are operated. Further, it is to be appreciated that amplifier modules of various power ratings can be constructed.

The balanced signals from the transformer T**1** are respectively provided to the gates of the transistors Q**1**, Q**2**. One balanced signal is provided to the gate of transistor Q**2** through a coupling capacitor C**2** and a resistor R**2**, for amplification by the transistor Q**2**. The other balanced signal is provided to the gate of transistor Q**1** through a coupling capacitor C**3** and resistor R**3**, for amplification by the transistor Q**1**. In an embodiment, capacitors C**2** and C**3** are each formed by two paralleled 47 nF capacitors and resistors R**2** and R**3** are each formed by four paralleled 15 ohm resistors.

A DC bias voltage for the gate of transistor Q**2** is provided at BIAS**2**. The bias voltage is provided to the gate of transistor Q**2** through an RF choke RFC**2** and resistor R**4**. A capacitor C**4** is connected to the RF choke RFC**2** and resistor R**4**, and also to ground, and provides a low impedance path to ground for high frequency signals. In an embodiment, the RF choke RFC**2** has a value of 10 μH. The DC bias voltage for the gate of transistor Q**2** can be provided by a temperature compensating bias circuit.

Similarly, a DC bias voltage for the gate of transistor Q**1** is provided at BIAS**1**. The DC bias voltage BIAS**1** is provided to the gate of transistor Q**1** through an RF choke RFC**1** and resistor R**5**. A capacitor C**5** is connected to the RF choke RFC**1** and resistor R**5**, and also to ground. The capacitor C**5** provides a low impedance path to ground for high frequency signals. In an embodiment, the RF choke RFC**1** has a value of 10 μH. The DC bias voltage for the gate of transistor Q**1** can be provided by a temperature compensating bias circuit. Temperature compensating bias circuits are shown in FIG. **4**, FIG. **5** and FIG. **9** and are discussed further below.

In an embodiment, capacitors C**4** and C**5** are each formed by two paralleled 47 nF capacitors and resistors R**4** and R**5** are each formed by four paralleled 110 ohm resistors.

The gates of the transistors Q**1**, Q**2** are respectively connected to ground through resistors R**7** and R**6**, which provide a discharge path for the charge on the gates when DC bias is removed, and provide a solid ground reference for the DC bias voltages for the gates. The respective sources of transistors Q**1** and Q**2** are directly connected to ground. In an embodiment, resistors R**6** and R**7** each have a value of 10 kΩ.

As shown in FIG. **2**, a DC power source that is greater than 50 VDC is connected to the drain of each transistor Q**1**, Q**2** through a common mode choke T**2**. Coils L**1** and L**2** of the common mode choke T**2** are connected such that magnetic flux is cancelled during each RF cycle, to minimize the net flux inside of the choke and, therefore, minimize the size of its core. A coil L**3**, which is an additional winding of the common mode choke, provides a negative feedback signal from the DC feed structure. Coil L**3** can be provided by a single turn through the center of the core of the common mode choke T**2**. Negative feedback serves to lower the input impedance and to stabilize the amplifier's gain over its frequency range. A feedback path for the gate of transistor Q**1** is provided through a network that includes resistor R**9** and either capacitor C**7** or optionally capacitor C**9**. A feedback path for the gate of transistor Q**2** is provided through a network that includes resistor R**10** and either capacitor C**8** or optionally capacitor C**10**. In an embodiment, capacitors C**7** and C**8** are each formed by two paralleled 47 nF capacitors while capacitors C**9** and C**10** are not used, and resistors R**9** and R**10** are each formed by four paralleled 36 ohm resistors.

It is to be appreciated that coil L**3** may be omitted and that negative feedback may be taken directly from the drains of the transistors Q**1** and Q**2**. In such a configuration, the feedback resistors R**9** and R**10** will be made physically larger because the voltage at the drains is proportionally larger by the winding ratio of coil L**3** to T**2**. More specifically, the voltage from coil L**3** is proportional to the ratio of L**3** turns divided by the sum of the turns of coils L**1** and L**2** times the RF drain-to-drain voltage applied to the primary low impedance side of transformer T**3** (transformer T**3** is discussed in detail below). For example if coil L**3** is one turn and L**1** and L**2** are each eight turns, the voltage available from L**3** is 1/16th of the drain-to-drain RF voltage.

The DC power source is connected to the common mode choke T**2** through a network that includes inductors L**4** and L**5**, a capacitor C**6** and a resistor R**8**. The inductors L**5** and L**6** provide a high impedance to RF signals and a short circuit for the DC power source. RF signals are decoupled from the DC power source by conduction to ground through the resistor R**8** and the capacitor C**6**. Inductors L**4** and L**5** can be ferrite bead inductors. In an embodiment, inductor L**5** is a wound ferrite core with a value of 10 μH, and capacitor C**6** is formed by six paralleled 47 nF capacitors. In addition to capacitor C**6**, similar grounded capacitors can be provided between inductor L**4** and the DC power source, and between inductor L**5** and the common mode choke T**2**. If, in addition to capacitor C**6**, similar grounded capacitors are provided between inductor L**5** and common mode choke T**2**, then resistor R**8** can be omitted. Sometimes, in an effort to increase isolation between the drains, the common DC feed point terminal of the common mode choke T**2** is split, and each winding is fed by identical decoupling networks similar to inductor L**5**, resistor R**8**, capacitor C**6**, and inductor L**4**. In such a configuration, the resistors need to be twice the value of resistor R**8** because they are AC paralleled. If in addition to capacitor C**6** similar grounded capacitors are used at the DC feed terminals of the common mode choke T**2**, the resistors can be omitted.

A broadband transmission line output transformer T**3** is connected to the drain of each transistor Q**1**, Q**2** and combines the amplified RF signals from each transistor Q**1**, Q**2**. The transformer T**3** is a balanced-to-balanced transformer having respective balanced inputs **25**, **26** connected to the drains of the transistors Q**1**, Q**2**. In FIG. **2**, balanced input **25** is directly connected to the drain of transistor Q**1**, and balanced input **26** is directly connected to the drain of transistor Q**2**. However, it is to be appreciated that DC-blocking capacitors could be provided between the balanced inputs **25**, **26** and the drains of the transistors Q**1**, Q**2**. The transformer T**3** has an input to output impedance ratio of 1:4 and performs an impedance matching function. In an embodiment, the characteristic impedance of the transistor output circuitry is 12.5 ohms. The transformer T**3** combines the outputs from the transistors Q**1**, Q**2** and steps the characteristic impedance of the circuit up to 50 ohms.

Transformer T**3** can be constructed using suitable cores, for example, toroid or ferrite tube cores, and coaxial cables having a characteristic impedance of approximately or exactly 25 ohms. Each coaxial cable can be wound on its own core. 25 ohms is the geometric mean of a 12.5 ohm input and a 50 ohm output. Performance of the transformer T**3** is enhanced when the characteristic impedance of the transformer's cables is the geometric mean of the input and output impedances. In an embodiment, the transformer T**3** includes coaxial cables having a characteristic impedance of 25 ohms, a size 16 AWG stranded center conductor, TEFLON® insulation between an outer braid and the center conductor, and an insulating jacket. The 25 ohm transmission line used to construct the transformer T**3** can also be constructed by paralleling standard 50 ohm coaxial cable. Further, the transmission line used to construct the transformer T**3** may be constructed from parallel magnet wire or parallel twisted TEFLON®-insulated wire.

As stated above, the transformer T**3** is a balanced-to-balanced transformer. There is essentially zero net flux within the cores of the transformer T**3** because the currents in its transmission lines travel in opposite directions, which gives rise to identical fluxes of opposite sense. It is to be appreciated that in a balanced-to-unbalanced or unbalanced-to-unbalanced transformer, the flux cancellation is not as complete. Therefore, the cores of the transformer T**3** can be made smaller than those used in a balanced-to-unbalanced or unbalanced-to-unbalanced transformer. Smaller transformer cores allow for shorter windings, thereby increasing the high frequency response of the transformer T**3**. Also, smaller transformer cores can accommodate a greater number or windings, resulting in increased inductance, which extends the lower frequency range of the transformer, such as to 1 MHz for example. In an embodiment, transformer T**3** has an operating frequency range of 1-60 MHz.

One benefit of using a 1:4 impedance ratio transmission line transformer as an RF output transformer, as shown in FIG. **2**, is that such a transformer is less difficult to construct than other transformers. A transformer having a 1:4 impedance ratio has an integer turns ratio of 1:2 and, therefore, does not require a winding tap. Such a transformer is less difficult to construct than a transformer having an impedance ratio of 1:2, which has a non-integer turns ratio of 1:1.414. However, in order to utilize a 1:4 impedance ratio transformer as an RF output transformer in a 600 watt push-pull amplifier module, transistors that operate with a drain-to-source voltage that is greater than 50 VDC must be used, rather than conventional 50 VDC MOSFETs.

An optional compensation capacitor C**11** is connected across the balanced input terminals **25**, **26** of the transformer T**3**, and provides a low-pass filter response by absorbing the inductance of T**3** and any output capacitance of the transistors Q**1**, Q**2**. This helps compensate for gain slope reduction at the high end of the amplifier module's frequency range.

The balanced outputs of transformer T3 are connected to an optional output balun transformer T4 through DC-blocking capacitors C12, C13. Capacitor C12 is connected between one output of transformer T3 and one input of balun transformer T4. Capacitor C13 is connected between the other output of transformer T3 and the other input of balun transformer T4. The capacitors C12, C13 and balun transformer T4 are connected in series between transformer T3 and the RF output terminal 24. In the embodiment of FIG. 2, the capacitors C12, C13 are located at the output, 50 ohms side of transformer T3, and between transformer T3 and balun transformer T4. By locating the DC-blocking capacitors at the output, 50 ohms side of transformer T3, rather than at the input side, the capacitors C12, C13 can be designed to handle a lower current. Such capacitors may be less expensive than capacitors designed to handle a higher current. The optional output balun transformer T4 has an impedance ratio of 1:1 and is connected to RF output terminal 24. In an embodiment, the output balun transformer T4 is constructed using 50 ohm coaxial cable and a ferrite core. Alternatively, transformer T4 may be formed by paralleled magnet wire or by parallel or twisted TEFLON®-insulated wire. By locating the DC-blocking capacitors C12, C13 between transformers T3 and T4, the RF output terminal 24 can be directly connected to the output balun transformer T4 and installed directly on a ground plane 27 of the printed circuit board 22. It is to be appreciated that the output balun transformer T4 is optional and can be omitted in some applications. However, omitting the output balun transformer T4 may result in reduced efficiency and/or increased intermodulation distortion (IMD).

A further schematic view of the broadband output transformer T3, the DC-blocking capacitors C12, C13, and the output balun transformer T4 is provided at FIG. 2*a*. In FIG. 2*a*, the broadband output transformer T3 and output balun transformer T4 are schematically shown as comprising coaxial cables. The output balun transformer T4 is shown having a coaxial cable shield connected to ground and a coaxial cable center conductor connected to the RF output terminal 24. It is to be appreciated that the output balun transformer T4 can be reversely connected, so that the coaxial cable shield is connected to the RF output terminal 24 and the coaxial cable center conductor connected to ground. The high impedance output side of the broadband output transformer T3 is connected the output balun transformer T4 through the DC-blocking capacitors C12, C13. In FIG. 2*a*, at the high impedance output side of transformer T3, the coaxial cable center conductors are shown as directly connected together, and the coaxial cable shields are connected to respective DC-blocking capacitors C12, C13. It is to be appreciated that the high impedance output side of transformer T3 can be reversely connected, so that its coaxial cable shields are directly connected together, and the coaxial cable center conductors are connected to respective DC-blocking capacitors C12, C13.

In an embodiment, capacitors C12 and C13 are each formed by six paralleled 47 nF capacitors.

FIG. 3 shows another embodiment of a push-pull amplifier module 31. Various components shown in FIG. 3 are discussed above with respect to FIG. 2. Such components are referenced in FIG. 3 by identical reference characters as used in FIG. 2 and are not discussed in detail below.

A plurality of transistors having grounded sources and directly interconnected drains form each half of the push-pull amplifier. For example, two transistors Q3, Q4 form the "push" half of the amplifier and two transistors Q5, Q6 form the "pull" half of the amplifier. The transistors Q3-Q6 can have output power ratings of at least 100 watts and operate with a drain-to-source voltage that is greater than 50 VDC. An example 100 watt transistor is model ARF463 manufactured by ADVANCED POWER TECHNOLOGY®. An amplifier module 31, having four 100 W transistors Q3-Q6 can have a power rating of 400 W. An amplifier module 31 having four 150 watt transistors Q3-Q6 can have a power rating of 600 watts. An amplifier module 31 having four 300 watt transistors Q3-Q6 can have a power rating of 1200 watts. In additional embodiments, each half of the push-pull amplifier includes more than two transistors. It is to be appreciated that amplifier modules of various power ratings can be constructed, based on the power rating of the selected transistors, the drain-to-source voltage at which the transistors are operated, and the number of transistors provided in each half of the push-pull amplifier.

An RF signal to be amplified by the amplifier module 31 is provided at the RF input terminal 23. The RF signal is transmitted to the transformer T1 and split into balanced RF signals at the output of transformer T1.

The balanced RF signals from transformer T1 are respectively provided to transformers T5 and T6. Transformers T5 and T6 are so-called Type 1 Splitters, which further split the RF signals. The respective split signals from transformer T5 are provided to transformers T7 and T8, which are impedance matching transformers having an input-to-output impedance ratio of, for example, 1:4. The RF signal that is output from impedance matching transformer T7 is provided to the gate of transistor Q3 through DC-blocking capacitor C21 and resistor R21. Similarly, the RF signal that is output from impedance matching transformer T8 is provided to the gate of transistor Q4 through DC-blocking capacitor C22 and resistor R22. In an embodiment, the DC-blocking capacitors C21 and C22 are each formed by two paralleled 47 nF capacitors.

The respective split signals from transformer T6 are provided to impedance matching transformers T9 and T10. The RF signal that is output from impedance matching transformer T9 is provided to the gate of transistor Q5 through DC-blocking capacitor C23 and resistor R23. Similarly, the RF signal that is output from impedance matching transformer T10 is provided to the gate of transistor Q6 through DC-blocking capacitor C24 and resistor R24. In an embodiment, the DC-blocking capacitors C23 and C24 are each formed by two paralleled 47 nF capacitors.

It is to be appreciated that a splitter utilizing resistors for further splitting the RF signals from transformer T1 could be used, rather than a Type 1 Splitter and impedance matching transformers as shown in FIG. 3.

A DC bias voltage for the gate of transistor Q3 is provided at BIAS3 and through a resistor R25, for example, a 15Ω resistor. A capacitor C25, for example, a 47 nF capacitor, provides a low impedance path to ground for high frequency signals. A DC bias voltage for the gate of transistor Q4 is provided at BIAS4 and through a resistor R26, for example, a 15Ω resistor. A capacitor C26, for example, a 47 nF capacitor, provides a low impedance path to ground for high frequency signals. A DC bias voltage for the gate of transistor Q5 is provided at BIAS5 and through a resistor R27, for example, a 15Ω resistor. A capacitor C27, for example, a 47 nF capacitor, provides a low impedance path to ground for high frequency signals. A DC bias voltage for the gate of transistor Q6 is provided at BIAS6 and through a resistor R28, for example, a 15Ω resistor. A capacitor C28, for example, a 47 nF capacitor, provides a low impedance path to ground for high frequency signals.

Feedback signals are provided from the common mode choke T2 via coil L3 through resistors R27 and R28. It is to be appreciated that negative feedback could be taken directly from the drains of the transistors Q**3**-Q**6**, which would require physically larger dissipation resistors R**27**, R**28**. In an embodiment, resistors R**27** and R**28** are each formed by two paralleled 430 ohm resistors.

Resistors R**29**-R**34** are balancing resistors for absorbing amplitude imbalance between the signal splitter outputs due to production tolerances. The resistors R**29**-R**34** also help to maintain correct input port impedance, contributing to a low voltage standing wave ratio (VSWR). In an embodiment, resistors R**29** and R**32** are each formed by two paralleled 51 ohm resistors, and resistors R**30**, R**31**, R**33**, and R**34** are each formed by two paralleled 15 ohm resistors.

Resistors R**35**-R**38** provide discharge paths for the charge on the gates when DC bias is removed, and provide solid ground references for the DC bias voltages for the gates. In an embodiment, resistors R**35**-R**38** each have a value of 10 kΩ.

The drains of transistors Q3 and Q4 are interconnected or directly connected together and are directly connected to an input **26** of transformer T**3**. The drains of transistors Q**5** and Q**6** are also interconnected or directly connected together and are directly connected to an input **25** of transformer T3. The "push" signal from transistors Q3 and Q4 are combined with the "pull" signal from transistors Q5 and Q6 by transformer T**3**.

FIG. **4** shows temperature compensating bias circuitry **40** for DC biasing the transistors that form the push-pull amplifiers discussed herein. In the amplifier shown in FIG. **2**, the DC bias voltage from the temperature compensating bias circuitry **40** would be provided at BIAS**1** and BIAS**2**. In the amplifier shown in FIG. **3**, the DC bias voltage from the temperature compensating bias circuitry **40** would be provided at BIAS3 through BIAS**6**.

The temperature of the transistors in the push-pull amplifiers will increase during operation of the amplifiers. To maintain a linear transistor operation at a constant idle point (bias current level), the temperature compensating bias circuitry **40** reduces the bias voltage of the transistors as their temperature increases. In an embodiment, the temperature compensating bias circuitry **40** is designed to reduce the bias voltage at a rate of 6.35 mV/° C.

The temperature compensating bias circuitry **40** includes a temperature sensor Q**41**. The output of the temperature sensor Q**41** changes with temperature. The temperature sensor Q**41** can be mounted so as to sense the temperature of the transistors in the push-pull amplifier. For example, the temperature sensor Q**41** can be attached to a heat sink for the transistors. In FIG. **4**, the temperature sensor Q**41** is a transistor and the temperature sensor provides a decreasing temperature signal level (e.g., −2.1 mV/° C.) as temperature increases. Alternatively, the temperature sensor could provide an increasing temperature signal level (e.g., 10 mV/° C.) as temperature increases. An example temperature sensor is a TIP31C power transistor. Another example temperature sensor is a temperature sensor integrated circuit (IC), such as an LM35 sensor from NATIONAL SEMICONDUCTOR®. It is to be appreciated that other types of temperature sensors could be incorporated into the temperature compensating bias circuitry **40**, such as resistive temperature devices (RTDs) or thermistors for example, and that the temperature compensating bias circuitry can include a plurality of temperature sensors mounted at different locations on or around the push-pull amplifier.

The temperature compensating bias circuitry **40** further includes a first amplifier U**41**, a second amplifier U**42**, a plurality of resistors R**41**-R**51**, and a potentiometer R**52**. The first and second amplifiers U**41**, U**42** can be operational amplifiers, such as the LM324A op-amp. The wiper of the potentiometer R**52** provides a bias output to supply the temperature compensated DC bias voltage to the transistors of the push-pull amplifier (not shown in FIG. **4**). In an embodiment, the potentiometer R**52** is a 5 kΩ potentiometer. Multiple potentiometers can be paralleled to provide individual bias control to each transistor in the push-pull amplifier. The first amplifier U**41** is configured to provide a first temperature dependent voltage to the potentiometer R**52** based on the temperature signal from the temperature sensor Q**41**. The second amplifier U**42** is configured to provide a second temperature dependent voltage based on the temperature signal to the potentiometer R**52** through resistor R**46**. The first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal. For example, both of the first temperature dependent voltage and the second temperature dependent voltage decrease at a rate of 6.35 mV/° C. Although the outputs of the amplifiers U**41**, U**42** change with increasing temperature, the voltage across the potentiometer remains substantially constant, which allows the full 6.35 mV/° C. voltage reduction to be provided, at any physical setting of the potentiometer, as reduced bias voltage to the push-pull amplifier's transistors (rather than a voltage divided percentage of 6.35 mV/° C. as established by the wiper setting of the potentiometer R**52**). An example first temperature dependent voltage from the first amplifier U**41** is 5.0 volts at 25° C. minus 6.35 mV/° C. An example second temperature dependent voltage from the second amplifier U**42** is 2.0 volts at 25° C. minus 6.35 mV/° C.

An example value for resistors R**41**, R**42**, R**45** and R**48** is 10.0 kΩ. An example value for resistor R**43** is 16.6 kΩ. An example value for resistor R**44** is 24.9 kΩ. An example value for resistor R**46** is 1 kΩ. An example value for resistor R**47** is 430 kΩ. An example value for resistor R**49** is 4.99 kΩ. An example value for resistor R**50** is 2 kΩ. An example value for resistor R**51** is 3.3 kΩ. A 5V input is shown as provided to resistors R**43**, R**47** and R**50**. The 5V input can be a programmable reference voltage and is not limited to 5V. In an embodiment, the 5V input is provided by an adjustable precision voltage reference, such as an LM385 available from NATIONAL SEMICONDUCTOR®.

FIG. **5** shows a further example of temperature compensating bias circuitry **50** for DC biasing the transistors that form the push-pull amplifiers discussed herein. The bias circuitry **50** includes an adjustable precision voltage reference D**51** and a temperature sensor Q**51**. With a 12 VDC supply **56** as shown, the bias circuitry is configured to supply a substantially constant 2.5 VDC across potentiometers R**52***a* and R**52***b*, while the first temperature dependent voltage **53** is 5.0 volts at 25° C. minus 6.35 mV/° C. and the second temperature voltage **54** is 2.0 volts at 25° C. minus 6.35 mV/° C. Supply 56 voltages other than 12 VDC (e.g., 8 VDC) could be used by the bias circuitry **50**. The bias circuitry **50** includes two bias outputs BIAS1, BIAS2 for supplying the temperature compensated DC bias voltage to the transistors of the push-pull amplifier (not shown in FIG. **5**). Example component values for resistors and capacitors in the bias circuitry **50** are shown in the figure. In FIG. **5**, amplifiers U**41** and U**42** feed transistors Q**53** and Q**54**, respectively, rather than feeding the potentiometers R**52***a* and R**52***b* directly. Transistors Q**53** and Q**54** are configured as followers and allow the amplifiers U**41** and U**42** to supply the necessary current when multiple potentiometers are used. An optional diode D**52** is provided at the output of amplifier U**42** to compensate for any ambient temperature-induced changes in the operation of the transistors Q**53** and Q**54**. Multiple diodes can be used instead of a single diode D**52** as shown, to compensate for ambient temperature-induced changes in the operation of other components, such as changes in the operation of the diodes located between the potentiometers R**52***a*, R**52***b* and the bias outputs BIAS**1**, BIAS**2**.

The temperature compensating bias circuitry **50** of FIG. **5** includes an amplifier U**51** that generates a temperature output signal **55**. The temperature output signal **55** transmits the temperature of the RF power amplifier module and can be monitored by a remote device and/or used to display a current temperature of the RF power amplifier module. The bias circuitry **50** can be configured so that the temperature output signal **55** increases at a constant rate, such as 50 mV/° C., or decreases at a constant rate over a voltage range (e.g., 0-5 VDC) corresponding to a temperature range (e.g., 2° C.-102° C.). The bias circuitry **50** can further be configured so that the temperature output signal **55** increases or decreases at a constant rate per bit of an analog to digital (A/D) converter (e.g., 1° F. per bit for an 8 bit ND). In FIG. **5**, the temperature output signal **55** is configured to be 5 VDC at 11.5° F. and 0 VDC at 266.5° F., which is 1° F. per bit for an 8 bit ND. It is to be appreciated that the amplifier U**51** can be configured to generate a positive going signal suitable for display on an analog meter.

The temperature compensating bias circuitry **50** of FIG. **5** further includes an amplifier U**52** (e.g., an operational amplifier) configured as a comparator that controls activations of transistor Q**52** based on the temperature signal from the temperature sensor Q**51**. When the temperature exceeds a set point or limit established by the voltage divider consisting of the 18K and 11.5K resistors, the comparator output causes the transistor Q**52** to conduct. This generates a high temperature alarm on a T LIMIT line **57**, to signal an off board controller (not shown) that a fault condition exists and that corrective action needs to be taken. A TRANSISTOR DUMP line **58** allows the off board controller to deactivate the transistors of the push-pull amplifier. The off board controller can deactivate the transistors of the push-pull amplifier based on monitored parameters, such as the temperature of the amplifier module. In the event of any fault, it is desirable for the RF transistors to stop amplifying as soon as possible. One way to do this is to shut the transistors off by removing bias and discharging the gates as soon as possible. Activation of a dump transistor Q**55** pulls the gates of the push-pull amplifier to ground through 10Ω resistors, which limit the discharge current to a safe level that will not damage transistor Q**55**.

It is to be appreciated that the use of quad op-amp ICs in the temperature compensating bias circuitry **50** will provide amplifiers U**41**, U**42**, U**51** and U**52** in a single package. The marginal cost increase of a quad op-amp IC versus a dual op-amp IC is typically small. Therefore, although amplifiers U**51** and U**52** are optional elements of the temperature compensating bias circuitry **50**, their addition should not increase the cost of the circuitry **50** very much, rendering the temperature output and the temperature alarm signals inexpensive to generate.

FIG. **9** shows a further example of temperature compensating bias circuitry **90** for DC biasing the transistors that form the push-pull amplifiers discussed herein. The bias circuitry **90** in FIG. **9** includes a temperature sensor IC **91** rather than using a transistor as a temperature sensor. The temperature sensor IC **91** provides an increasing temperature signal level as the temperature of the RF module increases (e.g., 10 mV/° C.). The bias circuitry **90** processes the increasing temperature signal level from the temperature sensor IC **91** to provide the DC bias outputs BIAS1 and BIAS2 for the transistors in the push-pull amplifiers (not shown), the temperature output signal **55**, and the high temperature alarm **57**. As compared to the bias circuitry **50** shown in FIG. **5**, transistors Q**53** and Q**54** are omitted from the bias circuitry **90** shown in FIG. **9**. However, the wipers of the potentiometers R**52***a*, R**52***b* are connected to transistors Q**92** and Q**93**, which function as followers and generate the DC bias outputs BIAS**1**, BIAS**2**. The emitters of the follower transistors Q**92**, Q**93** are grounded through a low value resistor to provide a low impedance source characteristic that provides low IMD. Further, in the bias circuitry **90** of FIG. **9**, the dump transistor Q**55** is connected to the "+" terminal of amplifier U**41**. When the dump transistor Q**55** is activated by the TRANSISTOR DUMP line **58**, it essentially forces amplifier U**41** to reduce its output to 0V, causing the voltage at the bias outputs to drop to a very low value below the gate threshold voltage of the push-pull amplifier transistors. The gates of the RF MOSFETs in the push-pull amplifiers then discharge through gate resistors (e.g., see resistors R**6** and R**7** in FIG. **2**). Because the transistor followers allow a very large amount of current to be applied to the RF transistor gate resistors, the gate resistors can be changed to a much lower value (example from 10 KΩ to 470Ω or even 100Ω) to decrease the discharge time of the RF transistor gates. The added benefit of the lower value gate resistor is an improvement in the IMD of the amplifier module.

FIG. **6** and FIG. **8** show modifications of the push-pull power amplifier module **21** of FIG. **2**. Various components shown in FIG. **6** and FIG. **8** are discussed above with respect to FIG. **2**. Such components are referenced in FIG. **6** and FIG. **8** by identical reference characters as used in FIG. **2** and are not discussed in detail below.

In FIG. **6**, the DC-blocking capacitors C**12**, C**13** are replaced with DC-blocking transformers T**61** and T**62**, and the common mode choke T**2** is omitted. The DC-blocking capacitors C**12**, C**13** can be a source of failure in the power amplifier module **21** when they are subject to very high RF currents. Performance and reliability of the power amplifier module **21** can be improved by using DC-blocking transformers rather than capacitors.

The DC-blocking transformers T**61**, T**62** are respectively connected between the drains of transistors Q**1** and Q**2** and the balanced inputs **25**, **26** of the broadband output transformer T**3**. A negative feedback signal from the DC feed structure is provided by the DC-blocking transformers T**61**, T**62** as shown. The negative feedback can be provided by a single turn of wire through the centers of the cores of the DC-blocking transformers T**61**, T**62**. See FIG. **7**, which provides a schematic diagram of the DC-blocking transformers T**61**, T**62**.

Optional matching coils LM**1** and LM**2** can be located between the DC-blocking transformers T**61**, T**62** and the drains of the transistors Q**1**, Q**2**, and optional capacitors C**61** and C**62** can be located across the respective inputs of the DC-blocking transformers T**61**, T**62**. A bypass capacitor C**63** can be located at the DC power source. Optional capacitor C**6** provides further bypassing and can help improve balance of the system.

FIG. **7** schematically shows the construction of the DC-blocking transformers T**61**, T**62**. The DC-blocking transformers can be formed by winding coaxial cables **71**, **72** on respective cores **73**, **74**. In an embodiment, the coaxial cables have a characteristic impedance of 25 ohms, which is twice the drain-drain differential impedance of the transistors Q**1**, Q**2**. Connections to the center and shield conductors of the coaxial cables **71**, **72** are shown in FIG. **7**. The center and shield conductors are further identified in FIG. **6** by "C" and "S", respectively. The negative feedback loop **75** is also shown in FIG. **7**. It is to be appreciated that the center and shield connections can be transposed, and that the construction is not limited to coaxial cable (e.g., twisted wire pairs, paralleled wire, etc. can also be used). It is to be further appreciated that power and current handling capability of said 25Ω cable can be greatly increased by constructing the 25Ω cable by paralleling two 50Ω cables, preferably connecting the shield of one to the center of the other.

The input side of the DC-blocking transformers T**61**, T**62** is identified as "Balanced RF In" and the output side is identified as "Balanced RF Out." The shields of the coaxial cables **71**, **72** are connected to ground at the input side and, at the output side, provide the Balanced RF Out. The center conductors are connected to the drains of the transistors Q**1**, Q**2** through optional matching coils LM**1**, LM**2** (see FIG. **6**). The optional capacitors C**61**, C**62** (see FIG. **6**) are each connected between a center conductor and shield at the input side of the DC-blocking transformers T**61**, T**62**. The DC power source for the transistors Q**1**, Q**2** is connected to the center conductors of the cables **71**, **72** at the output side of the transformers T**61**, T**62**. The shields of the cables **71**, **72** provide the RF output signal to the broadband output transformer T**3** (see FIG. **6**) at the output side of the transformers T**61**, T**62**.

It is to be appreciated that the DC-blocking transformers T**61**, T**62** can be constructed from paralleled or twisted wire if desired.

FIG. **8** shows the push-pull power amplifier module **21** of FIG. **6** with the addition of transformer T**2***a*. Transformer T**2***a* generates the negative feedback signal for the transistors Q**1**, Q**2**, instead of the DC-blocking transformers T**61**, T**62**. Transformer T**2***a* can be connected on either side of the optional matching coils LM**1** and LM**2**. In an embodiment, the primary of transformer T**2***a* is a single turn loop. Optional capacitors C**81** and C**82** are also shown connected on either side of the output balun transformer T**4**.

In a configuration differing from FIG. **6**, FIG. **10** shows the DC-blocking transformers connected to a 12.5 ohm characteristic impedance, 1:1 impedance ratio balun T**101**, followed by a 1:4 impedance ratio unbalanced-to-unbalanced transformer T**102**. The balun T**101** is a broadband output transformer. Transformers T**3** and T**4** are eliminated in FIG. **10**.

As discussed above, the amplifier modules described herein can be combined to create higher-powered amplifiers. It is to be appreciated that the combiners used to combine the outputs of the amplifier modules can have a variety of output impedances, such as 12.5 ohm, 25 ohm, 50 ohm, 100 ohm, etc. The output impedance of the combiners can further be matched to a desired characteristic impedance, such as 50 ohm, using a transformer that provides the proper impedance matching.

FIG. **11** and FIG. **12** both show two amplifier modules being combined to create a higher-powered amplifier. A splitter **103** splits an input signal to two push-pull amplifier modules. The amplifier modules in FIG. **11** include DC-blocking capacitors C**12**, C**13**, whereas the amplifier modules in FIG. **12** include DC-blocking transformers T**61**, T**62**. In FIG. **11** and FIG. **12**, the output of each push-pull transistor pair in a module is fed to an output balun transformer T**104**, T**105**. The output balun transformers T**104**, T**105** can have an input-to-output impedance ratio of 1:1. The output balun transformers provide an output impedance of 25 ohms for each amplifier module. The output balun transformers T**104**, T**105** in FIG. **11** supply a combiner **106**. The combiner **106** combines the outputs from the amplifier modules into a combined signal. The combiner **106** includes a type 2 hybrid 0° 2-way combiner **107**, which supplies an unbalanced-to-unbalanced output transformer **108** having an input-to-output impedance ratio of 1:4. The output impedance of the type 2 hybrid 0° 2-way combiner **107** is 12.5 ohms, which is stepped up to a 50 ohm output impedance by the unbalanced-to-unbalanced output transformer **108**. The type 2 hybrid 0° 2-way combiner **107** supplies the combined signal to the unbalanced-to-unbalanced output transformer **108**.

The combiner **109** in FIG. **12** is similar to the combiner in FIG. **11**, except that the combiner **109** includes a type 1 0° hybrid combiner.

Example applications with which the disclosed modular RF power amplifier system may be used include radio communications, such as amateur radio communications, military radio communications, marine radio communications (e.g., ship to shore), high frequency radio telephone communications, and short wave radio broadcast stations.

It should be evident that this disclosure is by way of example and that various changes may be made by adding, modifying or eliminating details without departing from the fair scope of the teaching contained in this disclosure. The invention is therefore not limited to particular details of this disclosure except to the extent that the following claims are necessarily so limited.

What is claimed is:

1. An RF power amplifier, comprising:
- a first field effect transistor:
  - having a first gate, a first source, and a first drain,
  - having an output power rating of at least 200 watts, and
  - operating with a drain-to-source voltage that is greater than 50 VDC;
- a second field effect transistor:
  - having a second gate, a second source, and a second drain,
  - having an output power rating of at least 200 watts, and
  - operating with a drain-to-source voltage that is greater than 50 VDC;
  - wherein said transistors are configured as a push-pull amplifier;
- an RF signal input;
- an input transformer connected to the RF signal input, the input transformer having respective balanced outputs connected to the first gate and the second gate;
- a broadband output transformer having a first balanced input connected to the first drain, and a second balanced input connected to the second drain, wherein the broadband output transformer has an input to output impedance ratio of 1:4, and further wherein at least some flux cancellation occurs within the broadband output transformer; and
- temperature compensating bias circuitry for providing a temperature compensated bias voltage to the first field effect transistor and the second field effect transistor for decreasing the bias voltage of the first field effect transistor and the second field effect transistor as transistor temperature increases, the temperature compensating bias circuitry comprising:
  - a temperature sensor generating a temperature signal;
  - a first amplifier having an output providing a first temperature dependent voltage based on the temperature signal;
  - a second amplifier having an output providing a second temperature dependent voltage based on the temperature signal, wherein the first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal; and
  - a potentiometer connected to the output of the first amplifier and the output of the second amplifier such that a voltage across the potentiometer remains sub-

stantially constant when the first temperature dependent voltage and the second temperature dependent voltage change; and

a bias output connected to at least one of the first field effect transistor and the second field effect transistor and supplying the temperature compensated bias voltage to the at least one of the first field effect transistor and the second field effect transistor.

2. A modular RF power amplifier system, comprising:

a first amplifier module comprising the RF power amplifier as set forth in claim **1**; and

a second amplifier module comprising the RF power amplifier as set forth in claim **1**;

wherein outputs from said modules are combined to form a combined RF output.

3. The RF power amplifier of claim **1**, further comprising:

an RF output terminal;

an output balun transformer; and

a DC-blocking capacitor, wherein the output balun transformer and the DC-blocking capacitor are connected in series between the broadband output transformer and the RF output terminal,

wherein the broadband output transformer is a transmission line transformer including a cable having a characteristic impedance of approximately or exactly 25 ohms,

wherein the broadband output transformer has balanced outputs and during operation of the RF power amplifier a net flux within the broadband output transformer is substantially zero, and

wherein the output balun transformer has an input to output impedance ratio of 1:1 and a characteristic impedance of approximately or exactly 50 ohms.

4. An RF power amplifier, comprising:

a first plurality of field effect transistors having directly interconnected drains and respective output power ratings of at least 100 watts;

a second plurality of field effect transistors having directly interconnected drains and respective output power ratings of at least 100 watts;

wherein said transistors operate with a drain-to-source voltage that is greater than 50 VDC, and

wherein the first plurality of field effect transistors and the second plurality of field effect transistors together form a push-pull amplifier having an output power rating of at least 400 watts;

an RF signal input;

an input transformer connected to the RF signal input, the input transformer having respective balanced outputs connected to gates of the first plurality of field effect transistors and gates of the second plurality of field effect transistors; and

a broadband output transformer having a first balanced input connected to the drains of the first plurality of field effect transistors, and a second balanced input connected to the drains of the second plurality of field effect transistors, wherein the broadband output transformer has an input to output impedance ratio of 1:4, and further wherein at least some flux cancellation occurs within the broadband output transformer; and

temperature compensating bias circuitry for providing a temperature compensated bias voltage to the first plurality of field effect transistors and the second plurality of field effect transistors for decreasing the bias voltage of the first plurality of field effect transistors and the second plurality of field effect transistors as transistor temperature increases, the temperature compensating bias circuitry comprising:

a temperature sensor generating a temperature signal;

a first amplifier having an output providing a first temperature dependent voltage based on the temperature signal;

a second amplifier having an output providing a second temperature dependent voltage based on the temperature signal, wherein the first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal; and

a potentiometer connected to the output of the first amplifier and the output of the second amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage and the second temperature dependent voltage change; and

a bias output connected to at least one of the first plurality of field effect transistors and the second plurality of field effect transistors and supplying the temperature compensated bias voltage to the at least one of the first plurality of field effect transistors and the second plurality of field effect transistors.

5. A modular RF power amplifier system, comprising:

a first amplifier module comprising the RF power amplifier as set forth in claim **4**; and

a second amplifier module comprising the RF power amplifier as set forth in claim **4**, wherein outputs from said modules are combined to form a combined RF output.

6. The RF power amplifier of claim **4**, further comprising:

an RF output terminal;

an output balun transformer; and

a DC-blocking capacitor, wherein the output balun transformer and the DC-blocking capacitor are connected in series between the broadband output transformer and the RF output terminal,

wherein the broadband output transformer is a transmission line transformer including a cable having a characteristic impedance of approximately or exactly 25 ohms,

wherein the broadband output transformer has balanced outputs and during operation of the RF power amplifier a net flux within the broadband output transformer is substantially zero, and

wherein the output balun transformer has an input to output impedance ratio of 1:1 and a characteristic impedance of approximately or exactly 50 ohms.

7. An RF power amplifier, comprising:

a push-pull amplifier, the push-pull amplifier comprising a first field effect transistor and a second field effect transistor; and

temperature compensating bias circuitry for providing a temperature compensated bias voltage to the first field effect transistor and the second field effect transistor for decreasing the bias voltage of the first field effect transistor and the second field effect transistor as transistor temperature increases, the temperature compensating bias circuitry comprising:

a temperature sensor generating a temperature signal;

a first amplifier having an output providing a first temperature dependent voltage based on the temperature signal; and

a potentiometer connected to the output of the first amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage changes; and

a bias output connected to at least one of the first field effect transistor and the second field effect transistor and supplying the temperature compensated bias voltage to the at least one of the first field effect transistor and the second field effect transistor.

8. The RF power amplifier of claim **7**, wherein the temperature compensating bias circuitry further comprises a second amplifier having an output providing a second temperature dependent voltage based on the temperature signal,

wherein the first temperature dependent voltage and the second temperature dependent voltage change at substantially the same rate in response to the temperature signal, and

wherein the potentiometer is connected to the output of the first amplifier and the output of the second amplifier such that a voltage across the potentiometer remains substantially constant when the first temperature dependent voltage and the second temperature dependent voltage change.

9. The RF power amplifier of claim **8**, further comprising a follower transistor connected to the potentiometer, wherein the follower transistor generates the bias output.

10. The RF power amplifier of claim **7**, wherein the temperature sensor is a transistor.

11. The RF power amplifier of claim **7**, wherein the temperature sensor comprises a temperature sensor integrated circuit.

12. The RF power amplifier of claim **7**, further comprising a temperature output signal transmitting a temperature of the RF power amplifier.

13. The RF power amplifier of claim **7**, further comprising a transistor dump signal for deactivating at least one of the first field effect transistor and the second field effect transistor.

14. The RF power amplifier of claim **7**, wherein the first field effect transistor includes a first gate, a first source, and a first drain,

wherein the second field effect transistor includes a second gate, a second source, and a second drain, the RF power amplifier further comprising:

a broadband output transformer having a first balanced input and a second balanced input, wherein the broadband output transformer has an input to output impedance ratio of 1:4, and further wherein at least some flux cancellation occurs within the broadband output transformer;

a first DC-blocking transformer connected between the first balanced input and the first drain; and

a second DC-blocking transformer connected between the second balanced input and the second drain.

15. The RF power amplifier of claim **14**, wherein each one of the broadband output transformer, the first DC-blocking transformer, and the second DC-blocking transformer include a cable having a characteristic impedance of approximately or exactly 25 ohms.

16. The RF power amplifier of claim **14**, wherein the first DC-blocking transformer provides a negative feedback signal to the first field effect transistor, and wherein the second DC-blocking transformer provides a negative feedback signal to the second field effect transistor.

17. The RF power amplifier of claim **14**, further comprising another transformer, which provides negative feedback signals to the first field effect transistor and the second field effect transistor.

18. The RF power amplifier of claim **14**, further comprising an RF output terminal; and

an output balun transformer connected between the broadband output transformer and the RF output terminal.

19. An RF power amplifier, comprising:

a push-pull amplifier, the push-pull amplifier comprising a first field effect transistor having a first drain and a second field effect transistor having a second drain;

a broadband output transformer having a first balanced input and a second balanced input;

a first DC-blocking transformer connected between the first balanced input and the first drain; and

a second DC-blocking transformer connected between the second balanced input and the second drain.

20. The RF power amplifier of claim **19**, further comprising temperature compensating bias circuitry for providing a temperature compensated bias voltage to the first field effect transistor and the second field effect transistor for decreasing the bias voltage of the first field effect transistor and the second field effect transistor as transistor temperature increases.

21. The RF power amplifier of claim **19**, wherein each one of the broadband output transformer, the first DC-blocking transformer, and the second DC-blocking transformer include a cable having a characteristic impedance of approximately or exactly 25 ohms.

22. The RF power amplifier of claim **19**, wherein the first DC-blocking transformer provides a negative feedback signal to the first field effect transistor, and wherein the second DC-blocking transformer provides a negative feedback signal to the second field effect transistor.

23. The RF power amplifier of claim **19**, further comprising another transformer, which provides negative feedback signals to the first field effect transistor and the second field effect transistor.

24. The RF power amplifier of claim **19**, wherein the broadband output transformer has an input to output impedance ratio of 1:4, and further wherein at least some flux cancellation occurs within the broadband output transformer.

25. The RF power amplifier of claim **24**, further comprising an RF output terminal; and

an output balun transformer connected between the broadband output transformer and the RF output terminal.

26. The RF power amplifier of claim **19**, wherein the broadband output transformer has unbalanced outputs and an input to output impedance ratio of 1:1.

27. The RF power amplifier of claim **26**, further comprising an RF output terminal; and

an unbalanced-to-unbalanced transformer connected between the broadband output transformer and the RF output terminal.

28. The RF power amplifier of claim **27**, wherein the unbalanced-to-unbalanced transformer has an input to output impedance ratio of 1:4.

29. An RF power amplifier, comprising:

a first amplifier module comprising a first push-pull amplifier including a plurality of field effect transistors and a first output balun transformer, wherein an output impedance of the first amplifier module is 25 ohms;

a second amplifier module comprising a second push-pull amplifier including a plurality of field effect transistors and a second output balun transformer, wherein an output impedance of the second amplifier module is 25 ohms;

a combiner connected to the first amplifier module and the second amplifier module, the combiner comprising an unbalanced-to-unbalanced output transformer having an input-to-output impedance ratio of 1:4, wherein the combiner combines an output from the first amplifier module and an output from the second amplifier module into a combined signal,

wherein the combined signal is supplied to the unbalanced-to-unbalanced output transformer, and

wherein an output impedance of the combiner is 50 ohms.

30. The RF power amplifier of claim **29**, wherein the first amplifier module includes a plurality of DC-blocking transformers, and wherein the second amplifier module includes a plurality of DC-blocking transformers.

(57) **ABSTRACT**

An electric transmission system utilizes charge displacement for the wireless delivery of electric power. A transmitter for radiating a charge displacement current at a frequency of approximately 2 to 7 kHz to a receiver located remote from the transmitter. The receiver receives the charge displacement current and converts the current into a form of electric power usable by an electrical device coupled to the receiver. The transmitter may use a step up transformer with an input approximating a series of step function pulses at the intended transmission frequency to produce the required high voltage for transmission. The primary winding of the transformer is part of a tuned circuit having a resonant frequency higher than the frequency of the charge displacement current radiated.

METHOD AND APPARATUS FOR WIRELESS TRANSMISSION AND RECEPTION OF ELECTRIC POWER

The present invention relates to the field of electric energy transmission and distribution and specifically to a method and apparatus to deliver electric power to users wirelessly,

BACKGROUND OF THE INVENTION

Conventional electric power transmission and distribution to consumers involves a sophisticated system of transmission and distribution wires interconnected by transformers to raise or lower the voltage to appropriate levels during the delivery process. In addition, due to differing loads, capacitors and/or inductors may be switched into or out of the delivery circuits.

The costs to install and maintain the circuits are substantial. When new customers appear, new wiring must be installed to connect them to the transmission and distribution grid. In addition, there can be significant energy losses associated with the delivery, and spurious electromagnetic radiation can be developed which further degrades system performance and can create interference.

It is accordingly a purpose of the present invention to provide an electric power delivery system that avoids deficiencies of wired systems by utilizing a wireless transmission mechanism. Among the characteristics of such a system are a reduction or substantial elimination of electromagnetic radiation, and the ability to connect additional uses to the system at reasonable cost.

BRIEF DESCRIPTION OF THE INVENTION

In accordance with the foregoing and other objects and benefits, an electric power delivery system in accordance with the present invention utilizes the mechanism of charge displacement to transmit electric power from a generation site to a user. The system utilizes extremely low frequencies (ELF) to convey a current and utilizes the earth as a conductor. At the production end of the system conventionally generated electric current is converted into a charge displacement current and transmitted or broadcast wirelessly. A relatively simple receiving apparatus converts the charge displacement current back into a conventional alternating current flow at the location of a user, which current can then be utilized in the standard manner. With appropriate reception equipment, the charge displacement current can be received by moving vehicles, allowing direct receipt of a continuing flow of electrical power during operation.

BRIEF DESCRIPTION OF THE DRAWINGS

A fuller understanding of the invention will be achieved upon consideration of the following detailed illustrative description of a preferred embodiment of the invention when reviewed in conjunction with the annexed drawings, wherein:

FIG. **1**. is an illustration of a transmitter apparatus for generating an ELF charge displacement current in accordance with the invention;

FIG. **2** is a detail view of an interrupter electrode; and

FIG. **3** is an illustration of a receiver apparatus for receiving an ELF charge displacement current.

DETAILED DESCRIPTION OF THE INVENTION

The present invention incorporates the recognition that, based upon the electromagnetic characteristics of the earth and its surrounding ionosphere, an electrical energy transmission at a frequency in the range of about 2 to 7 kHz maximizes displacement charge transfer from a transmitting apparatus to the atmosphere and earth. The invention incorporates a transmitting element in the form of a capacitor plate that is part of a high voltage resonant circuit tuned to a frequency in the desired range to maximize transmitter efficiency to the atmosphere. The transmitting element is part of a transmitter system that converts electrical power, preferably at DC but typically at a low frequency, such as at mains frequency (60 Hz), and at a relatively low voltage, to the desired high voltage and frequency. The DC or mains frequency input power is pulsed at the desired transmission frequency and is applied to a tuned circuit resonant at a second frequency including a primary transformer winding as the tuned circuit's inductor. The transformer raises the voltage to the desired high voltage for transmission. To allow commercially-reasonably sized components to be used, the transformer is adapted to operate at a substantially higher frequency than the transmission frequency, typically at 50-100 kHz. The high voltage is passed to the transmission frequency-tuned resonant circuit including the transmitting element, allowing the 2 to 7 kHz pulses to be coupled to the earth and ionosphere to conduct the desired charge displacement.

With reference to FIG. **1**, generator room **10** houses a generator **12**. The generator is shown driven by a motor **14**, but other sources of motive power, such as a turbine, may be employed. A commercially available AC generator with a 60 Hz output can be utilized, but the lower the output frequency from the generator the lower losses due to mismatching and harmonic generation. While DC output is optimal, 60 Hz is sufficiently low to be acceptable.

The electrical output from the generator is fed to contactor **16**, allowing immediate shutdown of the transmitter to which the output is led in the event of a flashover or other problem in the transmitter room **26**. One line of the generator's output goes to one side of the parallel combination of capacitor **18**, coil **20** and one electrode assembly **22** of a rotary gap apparatus **24**, all located in the transmitter room. The other output line from the generator goes to the other side of capacitor **18** and coil **20** and to a second electrode assembly **22** of the rotary gap apparatus.

Capacitor **18** forms a first resonant or tuned circuit with coil **20**, the primary winding for transformer **66**, and the resonant frequency of which is given by $F=\frac{1}{2}\Pi\sqrt{L1C1}$. An acceptable value for the capacitor may be in the range of 0.27 uf and for the coil **20** an inductance in the range of 3 mH, which can be accommodated in a 6 foot high coil of 10 foot diameter. Capacitor **18** is chosen to have an appropriate working voltage and a low ESR (Equivalent Series Resistance), while coil **20** is of a conductor gauge appropriate for the current involved. The approximate resonant frequency for the listed component values is 75 kHz. The frequency is chosen to allow transformer **40**, of which coil **20** serves as a primary winding, to be of commercially-reasonable dimensions taking into account the current capacity of the turns, the voltage boost contemplated and the need to avoid flashover. As the voltage boost is great, it is generally desired that the number of turns for coil **20** be as low as possible to maintain a large turns ratio with minimal conductor mass.

The generator's output voltage is modulated by means of the rotary gap apparatus **24**, which is in parallel with capacitor **18** and coil **20**, and who's purpose is to generate a pulse train in the desired ELF range of 2-7 kHz. Rotary gap apparatus **24** comprises a nonconductive disc **28** supporting four or more electrodes **30** extending through the disc, evenly spaced along its perimeter. Two identical electrode assemblies **22**, spaced

180 degrees apart and positioned to align with the disc electrodes, are located at opposite sides of the disc, and are respectively connected to the generator output lines. As depicted in FIG. **2**, each electrode assembly **22** may consist of a conductive electrode **32** and a plurality of heat sink rings **34** along the electrode. The electrodes **32** are spaced about ¼ inch from the disc electrodes **30**; all the electrodes may be ½ inch in diameter. A motor **36** and transmission **38** rotates the disc **28** and attached electrodes. As the disc rotates its carried electrodes **30** pass by the electrode assemblies **22**, allowing current to bridge the inter-electrode gap at a frequency of two times the number of electrode **22** pairs. With a disc rotation speed of 7200 rpm and 2 electrode pairs, the modulation frequency is 3600 Hz. The rotary gap apparatus allows a pulse train approximating a series of step impulses to appear across the resonant circuit combination of capacitor **18** and coil **20**. Other means for developing the pulse train, such as an electronic switching circuit, can also be utilized, but must be capable of handling the large current appropriate for significant power transmission.

Coil **20** is wound about the base of a second coil **40** on an insulating form of sufficient diameter and height to allow the coil turns to form the appropriate inductance. The combination of the two coils forms transformer assembly **66** that is supported by insulators **42**. The turns ratio between primary coil **20** and secondary coil **40** is such that the output voltage of the generator is raised to several megavolts in coil **40**. One end of coil **40** is connected to ground, such as by series of grounding rods **44**, while the other (upper) end of the coil is connected to large conductive ring **46** forming a capacitor plate. Ring **46** is constructed and dimensioned to have the appropriate capacitance in free air to form a second resonant or tuned circuit with coil **40** at the same frequency as the resonant frequency of primary coil **20** and capacitor **18**. The inductance of coil **40** may be, for example, 14 mH, which can be accommodated in a coil with a diameter of 5 feet and a height of 10 feet. With the coil size and inductance determined, the dimensions for capacitor ring **46** to achieve the appropriate free air capacitance can be determined by those skilled in the art.

Transmitter assembly **48** consists of the series arrangement of a further coil **50**, likewise supported by insulators **42**, and second conductive ring **52** positioned at the top of the coil and the insulating form upon which it is constructed. The upper end of coil **40** is connected to the lower end of transmitter coil **50**, while conductive ring **52** is connected to the upper end of coil **50**. Ring **52** is constructed with dimensions, including its radius of curvature and its outside diameter, to yield a capacitance for the ring that, when combined with the inductance of coil **50**, create a resonant circuit whose frequency is equal to that of the pulse train generated by the rotary gap apparatus **24**, providing efficient coupling of the pulse train energy to the earth and ionosphere, and should preferably be of large capacitance relative to the capacitance of other system components. The radius of curvature of ring **52** should also be large enough so that the ring's surface electrical charge density, which is proportional to the voltage, capacitance and frequency, is small enough at the chosen high working voltage to prevent spark discharge into the surrounding atmosphere. It is contemplated that a ring of up to 200 feet in diameter may be appropriate. With the desired capacitance of the ring calculated, the inductance for coil **50** can be computed, and the physical characteristics of the coil, including number of turns and wire gauge, determined. As the combination of coil **50** and ring **52** is supported by insulators **42** they must be of sufficient size and height to prevent breakdown, even in damp weather.

Conductive ring **52** serves as the resonating element for coil **40**. Alternatively, the ring may also be constructed with a group of spaced discs around the entire outer circumference of the ring. Such a construction may prevent the buildup of eddy currents that otherwise may occur in the ring. Alternatively a series of small semicircular discs could be attached to the outside surface of the ring to provide the same effect.

It should be noted that the radiating element is not a dipole antenna, which would require a radiating element of dimensions specific to the wavelength of the transmitted frequency. Rather, the mechanism of transmission is charge displacement, not electromagnetic radiation. Thus, it is not necessary for the lines of flux to detach and close upon themselves to propagate an electric field. Instead, the lines of flux exist between two opposite charges, and the field is established by the lines of flux between the two points of charge. The force on each charge in dynes is given by:

$$F = \frac{q1q2}{4\rho e_o r^2} 10^5.$$

A relatively simple antenna and receiver system may be used to convert the radiated charge into useful energy. The antenna is designed as a terminating point for the field's flux lines. Therefore the antenna does not have to be a specific shape or length. A conversion unit is used in conjunction with the antenna to convert the field to normal 60 Hz electrical power, at which most electrical devices operate.

An illustrative antenna and receiver system is depicted in FIG. **3**. An antenna **54** is connected to one side of a large capacitance **56**. The other side of the capacitor is connected to a suitable ground or conductive surface acting as a ground plane **68**. The size of the antenna and ground plane, if not earth, have a bearing on the amount of power that can be extracted from the atmosphere, and thus should be sufficiently large for the intended draw. The receiving antenna is designed as a terminating point for the field's flux lines, thus the antenna does not have to be a specific shape or length. One side of coil **58** is connected to capacitor **56** through an electrical interrupter **60**, which preferably is electronic, rather than mechanical, and as known in the art can be either vacuum tube or solid state. The interrupter is tuned to the same pulse frequency as created by the transmitter's rotary gap apparatus **24**, and the combination of capacitor **56** and coil **58** form a resonant circuit likewise tuned to the pulse frequency. Coil **58** and second coil **62**, wound around coil **58** and consisting of fewer turns of a conductor, form a stepdown transformer, coil **58** having a wire size capable of carrying the induced current. Secondary coil **62** is connected to a conversion unit **64** as known in the art to convert the pulsating output current from the transformer to normal 60 Hz electrical power or to another frequency and voltage as appropriate for the electrical devices to be powered.

In addition to the obvious uses, such as supplying electricity to residential and commercial buildings, the transmission system of the present invention could also be used to power vehicles. The vehicle may be constructed of a non-conductive material such as fiberglass, and may have the collecting antenna located in the roof. A conversion unit would then convert the electrical energy as received to the form of electricity required by the vehicle's drive, typically an electric motor. The received energy could also be used to charge a battery array to provide power in the event the vehicle leaves a reception area.

The transmission system could also be used to power trains. Since a train system defines a given path, one or more transmitting stations could be set up to focus the broadcast power along the rail path. Those skilled in the art can appreciate that the present invention could likewise be used to deliver electric power to other specific locations and users, thus providing individualized delivery for power tools, outdoor appliances and any other electrical devices that use electricity.

We claim:

1. An electric transmission system, comprising a transmitter for radiating a charge displacement current at a frequency of from 2 to 7 kHz and a receiver located remote from the transmitter for receiving the charge displacement current and converting the current into a form of electric power usable by an electrical device coupled to the receiver, the transmitter including means for generating electrical power at a first low frequency, means for pulsing the power at the radiating frequency, transformer means for raising the voltage of the pulsed power to a high voltage for radiating, and a radiating element coupled to an output of the transformer.

2. The electric transmission system of claim **1**, wherein the transformer means includes a primary coil forming a part of a first tuned circuit.

3. The electric transmission system of claim **2**, wherein the first tuned circuit is in parallel with the pulsing means and is tuned to a higher frequency than the radiating frequency.

4. The electric transmission system of claim **3**, wherein the higher frequency is in the range of about 50-100 kHz.

5. The electric transmission system of claim **3**, wherein the transformer means includes a secondary coil forming a part of a second resonant circuit.

6. The electric transmission system of claim **5**, wherein the second tuned circuit is tuned to the same frequency as the first tuned circuit.

7. The electric transmission system of claim **6**, wherein the means for receiving the charge displacement current comprises an, antenna and a ground plane coupled to an interrupter in series with a tuned circuit.

8. The electric transmission system of claim **7**, wherein the tuned circuit includes a coil forming a primary side of a transformer and the converting means comprises a secondary side coil of the transformer coupled to a power converter.

9. The electric transmission system wherein of claim **8** the interrupter operates at the frequency of the charge displacement current and the tuned circuit is tuned to the frequency of the charge displacement current.

10. The electric transmission system of claim **5** wherein a third tuned circuit is tuned to the frequency of the displacement current, is coupled to the secondary coil of the transformer means, and includes the radiating element.

11. The electric transmission system of claim **10**, wherein the radiating element is a capacitor plate of the third tuned circuit.

12. The transmission system of claim **1**, wherein the receiver comprises means for receiving the charge displacement current and means coupled for converting the charge displacement current into electric power of a desired frequency and voltage.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more

around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected

to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the support structure;

providing a load with an electrical connection to the at least one collection device to passively draw current; and

powering a fuel cell between the support structure and the load, the powering performed with energy collected from the at least one collection device.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a diode electrically connected between the at least one collection device and the support structure.

9. The system of claim **8**, wherein the collection device comprises a diode.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising:

a switch connected in series between the at least one collection device and the load; and

a capacitor connected in parallel with the switch and the load.

15. The system of claim **14**, wherein the switch comprises an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

16. The system of claim **15**, further comprising a transformer connected between the interrupter and the load.

17. The system of claim **8**, further comprising:

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending;

means for passively inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

21. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a switch connected in series between the at least one collection device and the load, the switch comprising an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

22. The system of claim **21**, further comprising a transformer connected between the interrupter and the load.

23. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure, the collection device configured to passively draw current;

a load electrically connected to the at least one collection device;

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

24. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a fuel cell between the support structure and the load.

25. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

(57) **ABSTRACT**

An apparatus for perpetually harvesting ambient near ultraviolet to far infrared radiation to provide continual power regardless of the environment, incorporating a system for the harvesting electronics governing power management, storage control, and output regulation. The harvesting electronics address issues of efficiently matching the voltage and current characteristics of the different harvested energy levels, low power consumption, and matching the power output demand. The device seeks to harvest the largely overlooked blackbody radiation through use of a thermal harvester, providing a continuous source of power, coupled with a solar harvester to provide increased power output.

FIG. 7

INTEGRATED ELECTRONICS FOR PERPETUAL ENERGY HARVESTING

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH AND DEVELOPMENT

This invention was made in part with Government support under contract no. W31P4Q10C0034 awarded by US Army Aviation and Missile Command. The Government has certain rights in the invention.

CROSS-REFERENCE TO RELATED APPLICATIONS

Not Applicable

CROSS REFERENCE TO RELATED APPLICATIONS

None.

FIELD OF INVENTION

This invention pertains to the harvesting of ambient energy in the surrounding environment. More particularly this invention is related to a semiconductor perpetual energy harvesting and storage device and the harvesting electronics that control energy storage and output allowing the device to continually harvest and provide continuous power during both day and night in any environment.

BACKGROUND OF INVENTION

There are many sources of energy that can be converted into electrical energy. Sources that have been explored for harvesting are wind, temperature differences, motion, light energy and radio frequency energy. In all these energy situations, a specific situation must be present, such as air flow, temperature gradient, movement, sunlight, or transmitted RF, before energy can be harvested. When these situations do not occur, there is no source for energy to be harvested.

Harvesting ambient thermal energy has not been widely explored. The characteristic of thermal energy having a peak at long infrared wavelengths poses a significant challenge for harvesting. Additionally, power management, storage control, and regulation electronics must be developed to operate efficiently and respond to the power output demand.

BRIEF DESCRIPTION OF DRAWINGS

FIGS. **1**A and B depicts a high level structural representation of an energy harvesting system.

FIG. **2** depicts power available from blackbody radiation at various temperatures

FIG. **3** depicts the discharge characteristics of a lithium ion battery.

FIG. **4** depicts a block diagram of the harvester electronics utilizing a dual circuit design.

FIG. **5** depicts an alternate embodiment of a block diagram of the harvester electronics utilizing a dual circuit design.

FIG. **6** depicts a block diagram of the harvester electronics utilizing a single circuit design.

FIG. **7** depicts an alternate embodiment of a block diagram of the harvester electronics utilizing a single circuit design.

DETAILED DESCRIPTION

Reference is made in detail to the preferred embodiments of the invention. While the invention is described in conjunction with the preferred embodiments, the invention is not intended to be limited by these preferred embodiments. The contemplated embodiments for carrying out the present invention are described in turn with reference to the accompanying figures.

For purposes of the invention, radiation is defined to be the electromagnetic spectrum, particularly the near ultraviolet, visible, near infrared, short-wave infrared, mid-wave infrared, long-wave infrared and far infrared bands. The near ultraviolet band is comprised of wavelengths from about 300 to 400 nm. The visible light band is comprised of wavelengths from about 400 to 780 nm. The near infrared band is comprised of wavelengths from about 0.78 to 1 μm. The short-wave infrared band is comprised of wavelengths from about 1 to 3 μm. The mid-wave infrared band is comprised of wavelengths from about 3 to 6 μm. The long-wave infrared band is comprised of wavelengths from about 6 to 14 μm. The far infrared band is comprised of wavelengths from about 14 to 40 μm. However, the boundary between near ultraviolet radiation and visible light along with the boundary between visible light and infrared radiation is not precisely defined, resulting in overlap between the bands.

The term electrically connected is defined to encompass an electrical current flow, including bidirectional, unidirectional, or any hybrid current flow, such as an uneven current.

FIG. **1** depicts a high level structural configuration for an energy harvesting system. FIG. **1**A illustrates a cross section of the structural configuration. FIG. **1**B shows an exploded three dimensional view. The interconnects and electrodes in the structural configurations depicted in FIGS. **1**A and B are not shown.

The energy harvesting system comprises a solar harvester **105**, a thermal harvester **110**, a battery **115**, and harvester electronics **120**. The thermal harvester **110** is located between the solar harvester **105** and the battery **115**. The harvester electronics **120** is attached to the thermal harvester **110** on the same side as the battery **115**. The solar harvester **105** and thermal harvester **110** are electrically isolated from each other and individually electrically connected to the harvester electronics **120**. The battery **115** is electrically connected to the harvester electronics **120**.

The solar harvester **105** and the thermal harvester **110** may be comprised of a photovoltaic or photoelectrochemical system. The solar harvester **105** may include any photovoltaic system which absorbs radiation within the near ultraviolet, visible, or near infrared bands to generate power. The solar harvester **105** may be comprised of any type of solar cell, including traditional crystallized silicon solar cells, thin film solar cells, multi-layered solar cells, dye sensitized solar cells, or organic polymer solar cells. The material comprising the solar harvester may include, but is not limited to, amorphous silicon, polysilicon, crystalline silicon, Ge, SiGe, CdTe, ZnO, CdZnTe, HgCdTe, HgZnTe, GaAs, GaN, InP, GaSb, InSb, other semiconductors, light sensitive dyes, or polymers. A photovoltaic thermal harvester **105** may be comprised of a single junction or multiple junctions. The material comprising the thermal harvester **105** may include HgCdTe, HgZnTe, InSb, InAs, GaSb, GaAs, InP, PbTe, or polymers.

The battery **115** may be any type of rechargeable battery. One embodiment of the invention contemplates the use of solid state thin film battery may be comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, a single or multiple battery cells may be used. Optionally, in the case of multiple battery cells, the cells may be arranged in various configurations, e.g. series, parallel, etc. The battery **115** may be flexible, semi-flexible, or rigid. The battery **115** is electrically connected to the harvester electronics **120**.

The harvester electronics **120** may be comprised of circuitry which regulates the rate of charge and voltage level of the battery along with regulating the output of power to a load. In one embodiment of the invention, the harvester electronics may be comprised of a single chip integrated circuit. Optionally, the integrated circuits may be a CMOS circuit. Alternatively, an FPGA may be used for harvester electronics **120** to be configurable in the field. Optionally, the harvester electronics may be discretely integrated with the battery **115**. The harvester electronics may be flexible, semi-flexible, or rigid. The harvester electronics **120** may be powered by the battery **115**, energy from the solar harvester **105** or thermal harvester **110**, or a combination of energy sources.

The system is oriented to absorb radiation **100** arriving from the indicated direction, passing through the solar harvester **105** before reaching the thermal harvester **110**. The radiation **100** is comprised of the near ultraviolet, visible, near infrared, short-wave infrared, mid-wave infrared, long-wave infrared, and far infrared bands.

FIG. **2** illustrates the blackbody power as a function of wavelength at various temperatures. The blackbody radiation spectrum ranges from near ultraviolet to the infrared spectrum. Blackbody radiation has been largely overlooked as a potential energy source.

Blackbody radiation is a physical effect in which all objects at temperatures above 0 K emit electromagnetic power. The spectral radiance of an object is described through Planck's Law, which is presented as,

$$I(\lambda) = \frac{2hc^2}{\lambda^5\left(e^{\frac{hc}{\lambda kT}} - 1\right)},$$

where c is the speed of light, k is Boltzmann's constant, h is Planck's constant, λ is wavelength, and T is temperature in Kelvin of the object. By applying Lambert's cosine law to a hemispherical flux density from a flat surface, the maximum amount of incident radiation is equal to πI. This yields a maximum spectral radiance of

$$I(\lambda) = \frac{2\pi hc^2}{\lambda^5\left(e^{\frac{hc}{\lambda kT}} - 1\right)},$$

which best models the intensity of radiation from a planar source. As temperature increases, power (in watts per meters squared) increases at lower wavelengths. This results in the peak shifting towards lower wavelengths at higher temperatures.

As shown in FIG. **2**, at the temperatures ranging from −40° C. (233 K to +60° C., the peak power is at about 9 μm wavelength. Using Stefan-Boltzmann's law, $5.67\times10^{-8}\times T^4$, the total available blackbody radiation at a given temperature can be calculated. At room temperature, about 293 Kelvin, the total available blackbody radiation is estimated to be 413 W/m^2 with a peak between 7 to 10 μm.

FIG. **3** illustrates the discharge characteristics of a lithium-ion polymer cell at various currents. The figure shows that the cell maintains a relatively constant voltage, which drops sharply as the current decreases due to the battery's inherent resistance increasing. Given this characteristic of lithium-ion polymer cells, completely discharging cells, otherwise known as deep discharge, results in damage to the cells, which may include the inability to hold a charge and sustain a voltage across a load. To guard against this damage, low voltage protection is required. While the figure illustrates the characteristics for a 1.0 mAh grade lithium-ion polymer cell, the characteristics are similar for other lithium-ion polymer cells.

FIG. **4** illustrates a block diagram of the harvester electronics **120** utilizing a two circuit configuration. The harvester electronics **120** are comprised of a thermal harvester interface **400**, a solar harvester interface **405**, a battery manager **410**, and a voltage regulator **415**. Each component comprising the harvester electronics **120** may be electrically connected to and powered by the battery **115**. Optionally, the components of the harvester electronics **120** may be powered by the energy from the solar or thermal harvesters. Optionally, a combination of energy sources may be used to power the harvester electronics **120**. For example, the harvester electronics **120** may be powered by energy from the solar harvester **105** and the battery **115**.

The solar harvester **105** is electrically connected to the solar harvester interface **405**. The solar energy harvested by the solar harvester **105** is transferred to the solar harvester interface **405**. Optionally, the solar harvester interface may comprise a voltage boost to allow harvesting of solar energy at low voltages. Optionally, the voltage boost may be dynamically triggered below a certain threshold. The solar harvester interface is electrically connected to the battery manager **410**.

The thermal harvester **110** is electrically connected to the thermal harvester interface **400**. The thermal energy harvested by the thermal harvester **110** is transferred through the thermal harvester interface **400**. Due to the low voltage output of thermal energy, the thermal harvester interface **400** comprises a voltage boost. For example, the voltage boost may boost voltages from as low as 20 mV. The thermal harvester interface **400** is electrically connected to the battery manager **410**.

The solar harvester interface **405** and the thermal harvester interface **400** transfer the harvested energy to the battery manager **410**. The battery manager **410** merges the harvested energy from the solar harvester interface **405** and the thermal harvester interface **400**. This merged energy may be used to charge the battery **115** and/or be supplied to the electrically connected voltage regulator **415**. The battery manager **410** controls the rate of charge for the battery **115**. The rate of charge varies depending on the battery requirements. The battery manager **410** may be configured to disconnect the battery **115** from the output load when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. The voltage at which the battery manager **410** disconnects the battery varies depending on the battery specifications and configuration. For example, if the battery **115** is a lithium-ion polymer with discharge characteristics shown in FIG. **3**, the battery manager **410** will disconnect the battery from the load when the sharp voltage drop occurs. For example, but not to serve as a limitation, if the battery **115** is a 3.3 V lithium polymer battery, the battery manager **410** may be disconnect the battery from the load when the battery output voltage reaches 2.1 V. While the battery **115** is disconnected from the load, the battery manager **410** may continue to charge the battery **115** while providing power to the voltage regulator **415**.

Optionally, the battery manager **410** may include cell balancing capability when multiple battery cells are used. In the case where the battery cells have the same capacity, the battery manager **410** may differentially charge each cell to maximum capacity. In the case where the battery cells have varying capacities, the battery manager **410** may differentially charge each cell to maintain the same state of charge.

The battery manager **410** may be configured to disconnect the battery **115** when the battery is fully charged to prevent overcharging. In the situation where the battery **115** is fully charged and disconnected from further charging, the battery manager **410** will direct all the harvested energy to the voltage regulator **415**. In the absence of adequate power from the solar harvester **105**, the battery manager **410** may utilize the battery **115** to supplement power from the thermal harvester **110** to the voltage regulator **415**.

The voltage regulator **415** maintains a constant voltage level output, which enables the harvester electronics **120** to produce a regulated power output **420**. The voltage regulator **415** may be comprised of a Low Drop Out (LDO) DC-DC voltage regulator. Optionally, other linear voltage regulators or switching regulators may be used. For example, but not to serve as a limitation, other linear voltage regulators may comprise zener regulators, series regulators, transistor regulators, or regulators comprising an op-amp. The voltage regulator **415** may be modular and configured to match a specific range of output loads or increase power output drive capability.

Optionally, the components of the harvesting electronics may be specifically configured to efficiently supply adequate power depending on the specific applications. While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **5** illustrates an alternate embodiment of the harvester electronics utilizing a two circuit configuration. The solar harvester **105**, thermal harvester **110**, battery **115**, thermal harvester interface **400**, solar harvester interface **405**, battery manager **410**, and voltage regulator **415** are as described above in FIG. **1** and FIG. **4**.

The harvester electronics comprises a bandgap reference **500**. The bandgap reference **500** is electrically connected to and powered by the battery **115**. Optionally, the bandgap reference may be powered separately by the battery manager, not shown. The bandgap reference **500** provides a temperature independent voltage reference (REF) **505**. The bandgap reference is electrically connected to the battery manager **410** and voltage regulator **415**, along with the MPPT controls and charge pump controls comprising the thermal harvester interface **400** and solar harvester interface **405** and outputs the REF **505** to each of the components.

The solar harvester interface **405** and thermal harvester interface **400** may be further comprised of individual maximum power point tracking (MPPT) inputs **510**, MPPT controls **515**, charge pumps **520**, and charge pump controls **525**. The different harvesting conditions for solar and thermal harvesters may result in different circuitry comprising the aforementioned components. The aforementioned components comprising the individual harvester interfaces may be powered by the battery **115**. Optionally, the components may be powered by the battery manager **410** or the solar or thermal harvester.

The MPPT input **510** is electrically connected to and receives input from the solar or thermal harvester and MPPT control **515**. The MPPT input **510** may track to match the input impedance to the maximum harvesting input impedance to achieve the greatest possible power harvest, during moment to moment variations of light level, shading, temperature, and photovoltaic module characteristics based on the input from the MPPT control **515**.

The MPPT control **515** is electrically connected to and receives input from the solar or thermal harvester and bandgap reference **500**. The input from the bandgap reference **500** comprises the REF **505**. The MPPT control **515** indicates to the MPPT input **510** whether the operating voltage of the harvesting input has changed in a given direction and to adjust the impedance accordingly. Optionally, the MPPT control **515** may determine the disturbance of the operating voltage of the harvesting input through a logic algorithm utilizing the REF **505** and harvester inputs. The MPPT input **510** is electrically connected to and provides an output to the battery manager **410**.

Optionally, the MPPT input **510** may be electrically connected to the charge pump **520**. The charge pump **520** is electrically connected to and receives input from the MPPT input **510** and the charge pump control **525**. The charge pump **520** may be comprised of a capacitive charge pump. Alternatively, the charge pump **520** may be comprised of a step-up converter, boost converter, boost converter, another type of DC-DC converter, or a DC-AC converter coupled to a voltage multiplier. Optionally, the charge pump **520** may be comprised of multiple stages. For example, the charge pump **520** may pump from a voltage as low as 20 mV to over 4 V, using multiple stages to achieve the result.

The charge pump control **525** is electrically connected to and receives input from the bandgap reference **500** in the form of REF **505**. Based on the REF **505**, the charge pump control **525** may adjust the oscillator frequency and the number of charge pump stages used by the charge pump **520**, which may be none, one, or multiple stages.

In an embodiment where the components of the harvester electronics **120** is powered by the battery **115**, the output from the MPPT input **510** to the battery manager **410** may serve as a bypass in the situation where the battery **115** goes below the harvester electronics **120** operating voltage. If the battery **115** goes below the harvester electronics **120** operating voltage, the components may fail to function. This bypass may allow the battery manager to recover the device with a voltage input that could drive the harvest electronics **120** and charge the battery **115** above the minimum operating voltage.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **6** illustrates a block diagram embodiment of the harvester electronics **120** in a single circuit configuration. The thermal harvester **110** is electrically connected to a voltage boost **600**. The voltage boost **600** may be comprised of a capacitive charge pump. Alternatively, the voltage boost **600** may be comprised of a step-up converter, boost converter, boost converter, another type of DC-DC converter, or a DC-AC converter coupled to a voltage multiplier. The voltage boost increases the low voltage input from the thermal harvester. The voltage boost **600** is electrically connected to the charge control **605**. The charge control **605** controls the energy storage for a first battery **610**. The boosted energy from the thermal harvester **110** is used to charge the first battery **610**. The charge control **605** controls the rate of charge and the battery voltage level of the first battery **610**. When the first battery **610** is fully charged, the charge control **605** disconnects the battery to prevent overcharging.

The first battery **610** may be comprised of any type of rechargeable battery. One embodiment of the invention contemplates the use of solid state thin film battery may be comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, the first battery **610** may be comprised of single or multiple battery cells.

The first battery **610** is electrically connected to the power management block **615**. The power management block disconnects the first battery **610** from the output load when the battery when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. For example, if the first battery **610** comprises a lithium-ion polymer battery with discharge characteristics similar to the depiction in FIG. **3**, the power management block **615** will disconnect the battery from the load when the sharp voltage drop occurs. Additionally, the power management **615** is electrically connected to a second battery **620**. The power management block **615** regulates the output voltage of the first battery **610** to charge the second battery **620**. Optionally, the charge control **605** and the power management block **615** may be combined into a single block to regulate the storage and output of the first battery **610**.

The second battery **620** may be comprised of any type of rechargeable battery. One embodiment of the invention contemplates the use of a solid state thin film battery comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, the second battery **620** may be comprised of single or multiple battery cells. The second battery **620** is electrically connected to and receives solar energy input from the solar harvest regulator **625**.

The solar harvest regulator **625** is electrically connected to and receives input from the solar harvester **105**. Optionally, a zener protection diode may be used between the solar harvester **105** and solar harvest regulator **625** to protect the entire circuit. The solar harvest regulator **625** may comprise a mechanism to disconnect the second battery **620** once the battery reaches a full charge to prevent overcharging. Optionally, the solar harvest regulator **625** may be electrically connected to the voltage boost **600** and receives harvested thermal energy. Additionally, the solar harvest regulator **625** may comprise a voltage output regulator to disconnect the output when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. Optionally, the solar harvest regulator may comprise a LDO regulator, another type of linear voltage regulator, or a switching regulator to control the output to a load. For example, but not to serve as a limitation, other linear voltage regulators may comprise zener regulators, series regulators, transistor regulators, or regulators comprising an op-amp. Optionally the solar harvest regulator **625** may protect the second battery **620** from unintended discharge when the input is lower than the battery voltage. For example, a zener protection diode may be used as a mechanism, where the voltage of the solar input must match the voltage of the battery plus the zener diode voltage.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **7** illustrates an alternate block diagram embodiment of the harvester electronics **120** in a single circuit configuration. The harvester electronics comprises a bandgap reference **700**. The bandgap reference **700** is electrically connected to and powered by the second battery **620**. Optionally, the bandgap reference may be powered separately by the solar harvest regulator **625**, not shown. The bandgap reference **700** provides a temperature independent voltage reference (REF) **705** output. The bandgap reference is electrically connected to the solar harvest regulator **625** and the MPPT control **715** for the thermal and solar harvester inputs and outputs the REF **505** to each of the components.

The MPPT input **710** is electrically connected to and receives input from the solar or thermal harvester and MPPT control **715**. The MPPT input **710** may track to match the input impedance to the maximum harvesting input impedance to achieve the greatest possible power harvest, during moment to moment variations of light level, shading, temperature, and photovoltaic module characteristics based on the input from the MPPT control **715**.

The MPPT control **715** is electrically connected to and receives input from the solar or thermal harvester and bandgap reference **700**. The input from the bandgap reference **700** comprises the REF **705**. The MPPT control **715** indicates to the MPPT input **710** whether the operating voltage of the harvesting input has changed in a given direction and to adjust the impedance accordingly. Optionally, the MPPT control **715** may determine the disturbance of the operating voltage of the harvesting input through a logic algorithm utilizing the REF **705** and harvester inputs.

Optionally, in another embodiment of the invention, a second bandgap reference, not shown, may be connected to the charge control **605** and the first battery **610**. The second bandgap reference is electrically connected to and provides a reference output to the MPPT control **715** connected to the thermal harvester **110**. This embodiment allows for individual MPPT tracking for different sources of harvested energy.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

While the aforementioned embodiments depict harvesting electronics which control the storage of energy and regulate output to a load for solar and thermal harvesters, the harvesting electronics may be configured to receive input from multiple sources of energy harvesting. Examples of other sources may include, but are not limited to, air flow, temperature gradient, movement and transmitted radio frequencies.

Whereas many alterations and modifications of the present invention will no doubt become apparent to a person of ordinary skill in the art after having read the foregoing description, it is to be understood that the particular embodiments shown and described by way of illustration are in no way intended to be considered limiting. Therefore, reference to the details of the preferred embodiments is not intended to limit their scope.

The embodiments were chosen and described in order to explain the principles and applications of the invention, thereby allowing others skilled in the art to utilize the invention in its various embodiments and modifications according to the particular purpose contemplated. The scope of the invention is intended to be defined by the claims appended hereto and their equivalents.

The expected practical use of the present invention is the novel integrated perpetual energy harvester with energy storage and harvesting electronics. The proposed invention may be used as a one chip solution to store power from multiple sources of energy harvesting and regulate the output to a load.

What is claimed is:

1. A perpetual energy harvester comprising:

a solar harvester;

a photovoltaic thermal harvester attached to the bottom of the solar harvester;

a battery in close proximity to the thermal harvester; and

a harvesting electronics in close proximity to the thermal harvester and individually electrically connected to the solar harvester, the thermal harvester, and the battery, wherein the harvesting electronics receives input in the form of energy from the solar harvester and the thermal harvester, controls the amount of energy stored in the battery, and regulates the output to a load.

2. The perpetual energy harvester in claim **1**, wherein said battery is selected from the group consisting of thin film lithium-ion, lithium-ion polymer, polymer, semiconductor, and flexible batteries.

3. The perpetual energy harvester in claim **1**, wherein the solar harvester is selected from the group consisting of traditional crystallized silicon solar cells, thin film solar cells, multi-layered solar cells, dye sensitized solar cells, and organic polymer solar cells.

4. The perpetual energy harvester in claim **1**,

wherein the photovoltaic thermal harvester is comprised of material selected from the group consisting of HgCdTe, HgZnTe, InSb, InAs, GaSb, GaAs, InP, PbTe, and polymers.

5. A harvester electronics system comprising:

a thermal harvester interface, wherein the thermal harvester interface is electrically connected to and receives input from a thermal harvester;

a solar harvester interface, wherein the solar harvester interface is electrically connected to and receives input from a solar harvester;

a battery manager electrically connected to and receives input from the solar harvester interface and thermal harvester interface, wherein the battery manager is electrically connected to a battery and manages the energy stored in the battery; and

a voltage regulator electrically connected to the battery manager, wherein the voltage regulator receives an input from the battery manager and controls an output voltage to an external load.

6. The voltage regulator in claim **5**, further comprising a low drop out regulator.

7. The harvester electronics system in claim **5**, further comprising:

a bandgap reference electrically connected to the thermal harvester interface, the solar harvester interface, the battery manager, and the voltage regulator, wherein the bandgap reference outputs a temperature independent voltage reference to the thermal harvester interface, the solar harvester interface, the battery manager, and the voltage regulator.

8. The harvester electronics system in claim **7**, wherein said solar harvester interface comprises:

a Maximum Power Point Tracking (MPPT) input electrically connected to the solar harvester and the battery manager;

a MPPT control electrically connected to the solar harvester, the MPPT input, and the bandgap reference, wherein the MPPT control receives a voltage reference input from the bandgap reference and an input from the solar harvester, determines if the operating voltage has changed, and outputs instructions to the MPPT input which adjusts input impedance to match maximum harvesting input impedance;

a charge pump electrically connected to the MPPT input and the battery manager; and

a charge pump control electrically connected to the charge pump and the bandgap reference, wherein the charge pump control receives input from the bandgap reference and dynamically adjusts oscillation frequency for the charge pump.

9. The harvester electronics system in claim **8**, wherein the charge pump comprises one or more stages selected from the group consisting of a capacitive charge pump, a charge transfer switch, a step-up converter, and a boost converter, wherein the charge pump control dynamically adjusts the number of stages used by the charge pump based on the input from the bandgap reference.

10. The harvester electronics system in claim **7**, wherein said thermal harvester interface comprises:

a Maximum Power Point Tracking (MPPT) input electrically connected to the thermal harvester and the battery manager;

a MPPT control electrically connected to the thermal harvester, the MPPT input, and the bandgap reference, wherein the MPPT control receives a voltage reference input from the bandgap reference and an input from the thermal harvester, determines if the operating voltage has changed, and outputs instructions to the MPPT input which adjusts input impedance to match maximum harvesting input impedance;

a charge pump electrically connected to the MPPT input and the battery manager; and

a charge pump control electrically connected to the charge pump and the bandgap reference, wherein the charge pump control receives input from the bandgap reference and dynamically adjusts oscillation frequency for the charge pump.

11. The harvester electronic system in claim **10**, wherein said charge pump comprises one or more stages selected from the group consisting of a capacitive charge pump, a charge transfer switch, a step-up converter, and a boost converter, wherein the charge pump control dynamically adjusts the number of stages used by the charge pump based on the input from the bandgap reference.

12. A harvesting electronics system comprising:

a voltage boost electrically connected to a thermal harvester, wherein the voltage boost receives energy input from the thermal harvester;

a charge control electrically connected to the voltage boost, wherein the charge control receives energy input from the voltage boost;

a first battery electrically connected to the charge control, wherein the charge control regulates the energy storage of the first battery;

a power management block electrically connected to the first battery, wherein the power management block regulates the energy output of the first battery;

a second battery electrically connected to the power management block; and

a solar harvest regulator electrically connected to a solar harvester and the second battery, wherein the solar harvest regulator receives energy input from the solar harvester, regulates the energy storage of the second battery, and regulates the output to a load.

13. The harvesting electronics in claim **12**,

wherein the voltage boost comprises one or more stages selected from the group consisting of a capacitive charge pump, a charge transfer switch, a step-up converter, and a boost converter.

14. The harvesting electronics system in claim **12**, wherein:

the first battery is selected from the group consisting of thin film lithium-ion, lithium-ion polymer, polymer, semiconductor, and flexible batteries; and

the second battery is selected from the group consisting of thin film lithium-ion, lithium-ion polymer, polymer, semiconductor, and flexible batteries.

15. The harvesting electronics system in claim **12**, further comprising:

a zener protection diode between the solar harvester and the solar harvest regulator.

16. The harvesting electronics system in claim **12**, wherein the solar harvest regulator comprises a low drop out regulator.

17. The harvesting electronics system in claim **12**, further comprising:

a bandgap reference electrically connected to the second battery and the solar harvest regulator, wherein the bandgap reference outputs a temperature independent voltage reference to the solar harvest regulator.

18. The harvesting electronics system in claim **17**, comprising:

a first Maximum Power Point Tracking (MPPT) input electrically connected to the solar harvester, wherein the first MPPT input receives an energy input from the solar harvester;

a first MPPT control electrically connected to the solar harvester, the first MMPT input, and the bandgap reference, wherein the first MPPT control receives a voltage reference input from the bandgap reference and an input from the solar harvester, determines if the operating voltage has moved, and outputs instructions to the first MPPT input which adjusts input impedance to match maximum harvesting input impedance; and

a second MPPT input electrically connected to the thermal harvester, wherein the second MPPT input receives an energy input from the thermal harvester; and

a second MPPT control electrically connected to the thermal harvester, the second MMPT input, and the bandgap reference, wherein the second MPPT control receives a voltage reference input from the bandgap reference and an input from the thermal harvester, determines if the operating voltage has moved, and outputs instructions to the second MPPT input which adjusts input impedance to match maximum harvesting input impedance.

19. The harvesting electronics system in claim **12**, further comprising:

a first bandgap reference electrically connected to the second battery and the solar harvest regulator, wherein the first bandgap reference outputs a first temperature independent voltage reference to the solar harvest regulator; and

a second bandgap reference electrically connected to the first battery and the charge control, wherein the second bandgap reference outputs a second temperature independent voltage reference.

20. The harvesting electronics system in claim **19**, comprising:

a first Maximum Power Point Tracking (MPPT) input electrically connected to the solar harvester, wherein the first MPPT input receives an energy input from the solar harvester;

a first MPPT control electrically connected to the solar harvester, the first MMPT input, and the bandgap reference, wherein the first MPPT control receives the first temperature independent voltage reference input from the bandgap reference and an input from the solar harvester, determines if the operating voltage has moved, and outputs instructions to the first MPPT input which adjusts input impedance to match maximum harvesting input impedance; and

a second MPPT input electrically connected to the thermal harvester, wherein the second MPPT input receives an energy input from the thermal harvester; and

a second MPPT control electrically connected to the thermal harvester, the second MMPT input, and the bandgap reference, wherein the second MPPT control receives the second temperature independent voltage reference input from the bandgap reference and an input from the thermal harvester, determines if the operating voltage has moved, and outputs instructions to the second MPPT input which adjusts input impedance to match maximum harvesting input impedance.

(57) **ABSTRACT**

Radio frequency (RF) power amplifier (PA) circuitry and a PA envelope power supply are disclosed. The RF PA circuitry receives and amplifies an RF input signal to provide an RF output signal using an envelope power supply signal, which is provided by the PA envelope power supply. The RF PA circuitry operates in either a normal RF spectral emissions mode or a reduced RF spectral emissions mode. When reduced RF spectral emissions are required, the RF PA circuitry operates in the reduced RF spectral emissions mode. As such, at a given RF output power, during the reduced RF spectral emissions mode, RF spectral emissions of the RF output signal are less than during the normal RF spectral emissions mode. As a result, the reduced RF spectral emissions mode may be used to reduce interference between RF communications bands.

INTERFERENCE REDUCTION BETWEEN RF COMMUNICATIONS BANDS

PRIORITY CLAIMS

The present application claims priority to U.S. provisional patent application No. 61/489,487, filed May 24, 2011.

The present application claims priority to and is a continuation-in-part of U.S. patent application Ser. No. 13/090,663, filed Apr. 20, 2011, entitled "QUADRATURE POWER AMPLIFIER ARCHITECTURE," now U.S. Pat. No. 8,538,355, which claims priority to U.S. Provisional Patent Application No. 61/325,859, filed Apr. 20, 2010; No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010.

The present application claims priority to and is a continuation-in-part of U.S. Patent Application No. 13/172,371, filed Jun. 29, 2011, entitled "AUTOMATICALLY CONFIGURABLE 2-WIRE/3-WIRE SERIAL COMMUNICATIONS INTERFACE," now U.S. Pat. No. 8,983,409, which claims priority to U.S. Provisional Patent Applications No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, tiled Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. U.S. patent application Ser. No. 13/172,371 is a continuation-in-part of U.S. patent application Ser. No. 13/090,663, filed Apr. 20, 2011, which claims priority to U.S. Provisional Patent Applications No. 61/325,859, filed Apr. 20, 2010; No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7. 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010.

The present application claims priority to and is a continuation-in-part of U.S. patent application Ser. No. 13/198,074, filed Aug. 4, 2011, entitled "FREQUENCY CORRECTION OF A PROGRAMMABLE FREQUENCY OSCILLATOR BY PROPAGATION DELAY COMPENSATION," now U.S. Pat. No. 8,515,361, which claims priority to U.S. Provisional Patent Applications No. 61/370,554 filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. U.S. patent application Ser. No. 13/198,074 is a continuation-in-part of U.S. patent application Ser. No. 13/090,663, filed Apr. 20, 2011, which claims priority to U.S. Provisional Patent Applications No. 61/325,859, filed Apr. 20, 2010; No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; Ser. No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. U.S. patent application Ser. No. 13/198,074 is also a continuation-in-part of U.S. patent application Ser. No. 13/172,371, filed Jun. 29, 2011, which claims priority to U.S. Provisional Patent Applications No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010.

The present application claims priority to and is a continuation-in-part of U.S. patent application Ser. No. 13/226,831, filed Sep. 7, 2011, entitled "VOLTAGE COMPATIBLE CHARGE PUMP BUCK AND BUCK POWER SUPPLIES," which claims priority to U.S. Provisional Patent Application No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. U.S. patent application Ser. No. 13/226,831 is a continuation-in-part of U.S. patent application Ser. No. 13/090,663, filed Apr. 20, 2011, which claims priority to U.S. Provisional Patent Application No. 61/325,859, filed Apr. 20, 2010; No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. U.S. patent application Ser. No. 13/226,831 is also a continuation-in-part of U.S. patent application Ser. No. 13/172,371, filed Jun. 29, 2011, which claims priority to U.S. Provisional Patent Application No. 61/359,487, filed Jun. 29, 2010; No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010. In addition, U.S. patent application Ser. No. 13/226,831 is a continuation-in-part of U.S. patent application Ser. No. 13/198,074, filed Aug. 4, 2011, which claims priority to U.S. Provisional Patent Application No. 61/370,554, filed Aug. 4, 2010; No. 61/380,522, filed Sep. 7, 2010; No. 61/410,071, filed Nov. 4, 2010; and No. 61/417,633, filed Nov. 29, 2010.

All of the applications listed above are hereby incorporated herein by reference in their entireties.

FIELD OF THE DISCLOSURE

Embodiments of the present disclosure relate to radio frequency (RF) power amplifier (PA) circuitry, which may be used in RF communications systems.

BACKGROUND OF THE DISCLOSURE

As wireless communications technologies evolve, wireless communications systems become increasingly sophisticated. As such, wireless communications protocols continue to expand and change to take advantage of the technological evolution. As a result, to maximize flexibility, many wireless communications devices must be capable of supporting any number of wireless communications protocols, including protocols that operate using different communications modes, such as a half-duplex mode or a full-duplex mode, and including protocols that operate using different frequency bands. Further, the different communications modes may include different types of RF modulation modes, each of which may have certain performance requirements, such as specific out-of-band emissions requirements or symbol differentiation requirements. In this regard, certain requirements may mandate operation in a linear mode. Other requirements may be less stringent that may allow operation in a non-linear mode to increase efficiency. Wireless communications devices that support such wireless communications protocols may be referred to as multi-mode multi-band communications devices. The linear mode relates to RF signals that include amplitude modulation (AM). The non-linear mode relates to RF signals that do not include AM. Since non-linear mode RF signals do not include AM, devices that amplify such signals may be allowed to operate in saturation. Devices that amplify linear mode RF signals may operate with some level of saturation, but must be able to retain AM characteristics sufficient for proper operation.

A half-duplex mode is a two-way mode of operation, in which a first transceiver communicates with a second transceiver; however, only one transceiver transmits at a time. Therefore, the transmitter and receiver in such a transceiver do not operate simultaneously. For example, certain telemetry systems operate in a send-then-wait-for-reply manner. Many time division duplex (TDD) systems, such as certain Global System for Mobile communications (GSM) systems, operate using the half-duplex mode. A full-duplex mode is a simultaneous two-way mode of operation, in which a first transceiver communicates with a second transceiver, and both transceivers may transmit simultaneously. Therefore, the transmitter and receiver in such a transceiver must be capable of operating simultaneously. In a full-duplex transceiver, signals from the transmitter should not overly interfere with signals received by the receiver; therefore, transmitted signals are at transmit frequencies that are different from received signals, which are at receive frequencies. Many frequency division duplex (FDD) systems, such as certain wideband code division multiple access (WCDMA) systems or certain long term evolution (LTE) systems, operate using a full-duplex mode.

As a result of the differences between full duplex operation and half duplex operation, RF front-end circuitry may need specific circuitry for each mode. Additionally, support of multiple frequency bands may require specific circuitry for each frequency band or for certain groupings of frequency bands. FIG. **1** shows a traditional multi-mode multi-band communications device **10** according to the prior art. The traditional multi-mode multi-band communications device **10** includes a traditional multi-mode multi-band transceiver **12**, traditional multi-mode multi-band PA circuitry **14**, traditional multi-mode multi-band front-end aggregation circuitry **16**, and an antenna **18**. The traditional multi-mode multi-band PA circuitry **14** includes a first traditional PA **20**, a second traditional PA **22**, and up to and including an N^{TH} traditional PA **24**.

The traditional multi-mode multi-band transceiver **12** may select one of multiple communications modes, which may include a half-duplex transmit mode, a half-duplex receive mode, a full-duplex mode, a linear mode, a non-linear mode, multiple RF modulation modes, or any combination thereof. Further, the traditional multi-mode multi-band transceiver **12** may select one of multiple frequency bands. The traditional multi-mode multi-band transceiver **12** provides an aggregation control signal ACS to the traditional multi-mode multi-band front-end aggregation circuitry **16** based on the selected mode and the selected frequency band. The traditional multi-mode multi-band front-end aggregation circuitry **16** may include various RF components, including RF switches; RF filters, such as bandpass filters, harmonic filters, and duplexers; RF amplifiers, such as low noise amplifiers (LNAs); impedance matching circuitry; the like; or any combination thereof. In this regard, routing of RF receive signals and RF transmit signals through the RF components may be based on the selected mode and the selected frequency band as directed by the aggregation control signal ACS.

The first traditional PA **20** may receive and amplify a first traditional RF transmit signal FTTX from the traditional multi-mode multi-band transceiver **12** to provide a first traditional amplified RF transmit signal FTATX to the antenna **18** via the traditional multi-mode multi-band front-end aggregation circuitry **16**. The second traditional PA **22** may receive and amplify a second traditional RF transmit signal STTX from the traditional multi-mode multi-band transceiver **12** to provide a second traditional RF amplified transmit signal STATX to the antenna **18** via the traditional multi-mode multi-band front-end aggregation circuitry **16**. The N^{TH} traditional PA **24** may receive an amplify an N^{TH} traditional RF transmit signal NTTX from the traditional multi-mode multi-band transceiver **12** to provide an N^{TH} traditional RF amplified transmit signal NTATX to the antenna **18** via the traditional multi-mode multi-band front-end aggregation circuitry **16**.

The traditional multi-mode multi-band transceiver **12** may receive a first RF receive signal FRX, a second RF receive signal SRX, and up to and including an M^{TH} RF receive signal MRX from the antenna **18** via the traditional multi-mode multi-band front-end aggregation circuitry **16**. Each of the RF receive signals FRX, SRX, MRX may be associated with at least one selected mode, at least one selected frequency band, or both. Similarly, each of the traditional RF transmit signals FTTX, STTX, NTTX and corresponding traditional amplified RF transmit signals FTATX, STATX, NTATX may be associated with at least one selected mode, at least one selected frequency band, or both.

Portable wireless communications devices are typically battery powered, need to be relatively small, and have low cost. As such, to minimize size, cost, and power consumption, multi-mode multi-band RF circuitry in such a device needs to be as simple, small, and efficient as is practical. Thus, there is a need for multi-mode multi-band RF circuitry in a multi-mode multi-band communications device that is low cost, small, simple, efficient, and meets performance requirements.

SUMMARY OF THE EMBODIMENTS

Embodiments of the present disclosure relate to RF PA circuitry and a PA envelope power supply. The RF PA circuitry receives and amplifies an RF input signal to provide an RF output signal using an envelope power supply signal, which is provided by the PA envelope power supply. The RF PA circuitry operates in either a normal RF spectral emissions mode or a reduced RF spectral emissions mode. When reduced RF spectral emissions are required, the RF PA circuitry operates in the reduced RF spectral emissions mode. As such, at a given RF output power, during the reduced RF spectral emissions mode, RF spectral emissions of the RF output signal are less than during the normal RF spectral emissions mode. As a result, the reduced RF spectral emissions mode may be used to reduce interference between RF communications bands.

Those skilled in the art will appreciate the scope of the present disclosure and realize additional aspects thereof after reading the following detailed description of the preferred embodiments in association with the accompanying drawing figures.

BRIEF DESCRIPTION OF THE DRAWING FIGURES

The accompanying drawing figures incorporated in and forming a part of this specification illustrate several aspects of the disclosure, and together with the description serve to explain the principles of the disclosure.

FIG. **1** shows a traditional multi-mode multi-band communications device according to the prior art.

FIG. **2** shows an RF communications system according to one embodiment of the RF communications system.

FIG. **3** shows the RF communications system according to an alternate embodiment of the RF communications system.

FIG. **4** shows the RF communications system according to an additional embodiment of the RF communications system.

FIG. **5** shows the RF communications system according to another embodiment of the RF communications system.

FIG. **6** shows the RF communications system according to a further embodiment of the RF communications system.

FIG. **7** shows the RF communications system according to one embodiment of the RF communications system.

FIG. **8** shows details of RF power amplifier (PA) circuitry illustrated in FIG. **5** according to one embodiment of the RF PA circuitry.

FIG. **9** shows details of the RF PA circuitry illustrated in FIG. **5** according to an alternate embodiment of the RF PA circuitry.

FIG. **10** shows the RF communications system according to one embodiment of the RF communications system.

FIG. **11** shows the RF communications system according to an alternate embodiment of the RF communications system.

FIG. **12** shows details of a direct current (DC)-DC converter illustrated in FIG. **11** according to an alternate embodiment of the DC-DC converter.

FIG. **13** shows details of the RF PA circuitry illustrated in FIG. **5** according to one embodiment of the RF PA circuitry.

FIG. **14** shows details of the RF PA circuitry illustrated in FIG. **6** according to an alternate embodiment of the RF PA circuitry.

FIG. **15** shows details of a first RF PA and a second RF PA illustrated in FIG. **14** according to one embodiment of the first RF PA and the second RF PA.

FIG. **16** shows details of a first non-quadrature PA path and a second non-quadrature PA path illustrated in FIG. **15** according to one embodiment of the first non-quadrature PA path and the second non-quadrature PA path.

FIG. **17** shows details of a first quadrature PA path and a second quadrature PA path illustrated in FIG. **15** according to one embodiment of the first quadrature PA path and the second quadrature PA path.

FIG. **18** shows details of a first in-phase amplification path, a first quadrature-phase amplification path, a second in-phase amplification path, and a second quadrature-phase amplification path illustrated in FIG. **17** according to one embodiment of the first in-phase amplification path, the first quadrature-phase amplification path, the second in-phase amplification path, and the second quadrature-phase amplification path.

FIG. **19** shows details of the first quadrature PA path and the second quadrature PA path illustrated in FIG. **15** according to an alternate embodiment of the first quadrature PA path and the second quadrature PA path.

FIG. **20** shows details of the first in-phase amplification path, the first quadrature-phase amplification path, the second in-phase amplification path, and the second quadrature-phase amplification path illustrated in FIG. **19** according to an alternate embodiment of the first in-phase amplification path, the first quadrature-phase amplification path, the second in-phase amplification path, and the second quadrature-phase amplification path.

FIG. **21** shows details of the first RF PA and the second RF PA illustrated in FIG. **14** according an alternate embodiment of the first RF PA and the second RF PA.

FIG. **22** shows details of the first non-quadrature PA path, the first quadrature PA path, and the second quadrature PA path illustrated in FIG. **21** according to an additional embodiment of the first non-quadrature PA path, the first quadrature PA path, and the second quadrature PA path.

FIG. **23** shows details of a first feeder PA stage and a first quadrature RF splitter illustrated in FIG. **16** and FIG. **17**, respectively, according to one embodiment of the first feeder PA stage and the first quadrature RF splitter.

FIG. **24** shows details of the first feeder PA stage and the first quadrature RF splitter illustrated in FIG. **16** and FIG. **17**, respectively, according to an alternate embodiment of the first feeder PA stage and the first quadrature RF splitter.

FIG. **25** is a graph illustrating output characteristics of a first output transistor element illustrated in FIG. **24** according to one embodiment of the first output transistor element.

FIG. **26** illustrates a process for matching an input impedance to a quadrature RF splitter to a target load line of a feeder PA stage.

FIG. **27** shows details of the first RF PA illustrated in FIG. **14** according an alternate embodiment of the first RF PA.

FIG. **28** shows details of the second RF PA illustrated in FIG. **14** according an alternate embodiment of the second RF PA.

FIG. **29** shows details of a first in-phase amplification path, a first quadrature-phase amplification path, and a first quadrature RF combiner illustrated in FIG. **22** according to one embodiment of the first in-phase amplification path, the first quadrature-phase amplification path, and the first quadrature RF combiner.

FIG. **30** shows details of a first feeder PA stage, a first quadrature RF splitter, a first in-phase final PA impedance matching circuit, a first in-phase final PA stage, a first quadrature-phase final PA impedance matching circuit, and a first quadrature-phase final PA stage illustrated in FIG. **29** according to one embodiment of the first feeder PA stage, the first quadrature RF splitter, the first in-phase final PA impedance matching circuit, the first in-phase final PA stage, the first quadrature-phase final PA impedance matching circuit, and the first quadrature-phase final PA stage.

FIG. **31** shows details of the first feeder PA stage, the first quadrature RF splitter, the first in-phase final PA impedance matching circuit, the first in-phase final PA stage, the first quadrature-phase final PA impedance matching circuit, and the first quadrature-phase final PA stage illustrated in FIG. **29** according to an alternate embodiment of the first feeder PA stage, the first quadrature RF splitter, the first in-phase final PA impedance matching circuit, the first in-phase final PA stage, the first quadrature-phase final PA impedance matching circuit, and the first quadrature-phase final PA stage.

FIG. **32** shows details of first phase-shifting circuitry and a first Wilkinson RF combiner illustrated in FIG. **29** according to one embodiment of the first phase-shifting circuitry and the first Wilkinson RF combiner.

FIG. **33** shows details of the second non-quadrature PA path illustrated in FIG. **16** and details of the second quadrature PA path illustrated in FIG. **18** according to one embodiment of the second non-quadrature PA path and the second quadrature PA path.

FIG. **34** shows details of a second feeder PA stage, a second quadrature RF splitter, a second in-phase final PA impedance matching circuit, a second in-phase final PA stage, a second quadrature-phase final PA impedance matching circuit, and a second quadrature-phase final PA stage illustrated in FIG. **33** according to one embodiment of the second feeder PA stage, the second quadrature RF splitter, the second in-phase final PA impedance matching circuit, the second in-phase final PA stage, the second quadrature-phase final PA impedance matching circuit, and the second quadrature-phase final PA stage.

FIG. **35** shows details of second phase-shifting circuitry and a second Wilkinson RF combiner illustrated in FIG. **33** according to one embodiment of the second phase-shifting circuitry and the second Wilkinson RF combiner.

FIG. **36** shows details of a first PA semiconductor die illustrated in FIG. **30** according to one embodiment of the first PA semiconductor die.

FIG. **37** shows details of the RF PA circuitry illustrated in FIG. **5** according to one embodiment of the RF PA circuitry.

FIG. **38** shows details of the RF PA circuitry illustrated in FIG. **5** according to an alternate embodiment of the RF PA circuitry.

FIG. **39** shows details of the RF PA circuitry illustrated in FIG. **5** according to an additional embodiment of the RF PA circuitry.

FIG. **40** shows details of the first RF PA, the second RF PA, and PA bias circuitry illustrated in FIG. **13** according to one embodiment of the first RF PA, the second RF PA, and the PA bias circuitry.

FIG. **41** shows details of driver stage current digital-to-analog converter (IDAC) circuitry and final stage IDAC circuitry illustrated in FIG. **40** according to one embodiment of the driver stage IDAC circuitry and the final stage IDAC circuitry.

FIG. **42** shows details of driver stage current reference circuitry and final stage current reference circuitry illustrated in FIG. **41** according to one embodiment of the driver stage current reference circuitry and the final stage current reference circuitry.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The embodiments set forth below represent the necessary information to enable those skilled in the art to practice the disclosure and illustrate the best mode of practicing the disclosure. Upon reading the following description in light of the accompanying drawing figures, those skilled in the art will understand the concepts of the disclosure and will recognize applications of these concepts not particularly addressed herein. It should be understood that these concepts and applications fall within the scope of the disclosure and the accompanying claims.

FIG. **2** shows an RF communications system **26** according to one embodiment of the RF communications system **26**. The RF communications system **26** includes RF modulation and control circuitry **28**, RF PA circuitry **30**, and a DC-DC converter **32**. The RF modulation and control circuitry **28** provides an envelope control signal ECS to the DC-DC converter **32** and provides an RF input signal RFI to the RF PA circuitry **30**. The DC-DC converter **32** provides a bias power supply signal BPS and an envelope power supply signal EPS to the RF PA circuitry **30**. The envelope power supply signal EPS may be based on the envelope control signal ECS. As such, a magnitude of the envelope power supply signal EPS may be controlled by the RF modulation and control circuitry **28** via the envelope control signal ECS. The RF PA circuitry **30** may receive and amplify the RF input signal RFI to provide an RF output signal RFO. The envelope power supply signal EPS may provide power for amplification of the RF input signal RFI to the RF PA circuitry **30**. The RF PA circuitry **30** may use the bias power supply signal BPS to provide biasing of amplifying elements in the RF PA circuitry **30**.

In a first embodiment of the RF communications system **26**, the RF communications system **26** is a multi-mode RF communications system **26**. As such, the RF communications system **26** may operate using multiple communications modes. In this regard, the RF modulation and control circuitry **28** may be multi-mode RF modulation and control circuitry **28** and the RF PA circuitry **30** may be multi-mode RF PA circuitry **30**. In a second embodiment of the RF communications system **26**, the RF communications system **26** is a multi-band RF communications system **26**. As such, the RF communications system **26** may operate using multiple RF communications bands. In this regard, the RF modulation and control circuitry **28** may be multi-band RF modulation and control circuitry **28** and the RF PA circuitry **30** may be multi-band RF PA circuitry **30**. In a third embodiment of the RF communications system **26**, the RF communications system **26** is a multi-mode multi-band RF communications system **26**. As such, the RF communications system **26** may operate using multiple communications modes, multiple RF communications bands, or both. In this regard, the RF modulation and control circuitry **28** may be multi-mode multi-band RF modulation and control circuitry **28** and the RF PA circuitry **30** may be multi-mode multi-band RF PA circuitry **30**.

The communications modes may be associated with any number of different communications protocols, such as Global System of Mobile communications (GSM), Gaussian Minimum Shift Keying (GMSK), IS-136, Enhanced Data rates for GSM Evolution (EDGE), Code Division Multiple Access (CDMA), Universal Mobile Telecommunications System (UMTS) protocols, such as Wideband CDMA (WCDMA), Worldwide Interoperability for Microwave Access (WIMAX), Long Term Evolution (LTE), or the like. The GSM, GMSK, and IS-136 protocols typically do not include amplitude modulation (AM). As such, the GSM, GMSK, and IS-136 protocols may be associated with a non-linear mode. Further, the GSM, GMSK, and IS-136 protocols may be associated with a saturated mode. The EDGE, CDMA, UMTS, WCDMA, WIMAX, and LTE protocols may include AM. As such, the EDGE, CDMA, UMTS, WCDMA, WIMAX, and LTE protocols may be associated with a linear mode.

In one embodiment of the RF communications system **26**, the RF communications system **26** is a mobile communications terminal, such as a cell phone, smartphone, laptop computer, tablet computer, personal digital assistant (PDA), or the like. In an alternate embodiment of the RF communications system **26**, the RF communications system **26** is a fixed communications terminal, such as a base station, a cellular base station, a wireless router, a hotspot distribution node, a wireless access point, or the like. The antenna **18** may include any apparatus for conveying RF transmit and RF receive signals to and from at least one other RF communications system. As such, in one embodiment of the antenna **18**, the antenna **18** is a single antenna. In an alternate embodiment of the antenna **18**, the antenna **18** is an antenna array having multiple radiating and receiving elements. In an additional embodiment of the antenna **18**, the antenna **18** is a distribution system for transmitting and receiving RF signals.

FIG. **3** shows the RF communications system **26** according to an alternate embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **3** is similar to the RF communications system **26** illustrated in FIG. **2**, except in the RF communications system **26** illustrated in FIG. **3**, the RF modulation and control circuitry **28** provides a first RF input signal FRFI, a second RF input signal SRFI, and a PA configuration control signal PCC to the RF PA circuitry **30**. The RF PA circuitry **30** may receive and amplify the first RF input signal FRFI to provide a first RF output signal FRFO. The envelope power supply signal EPS may provide power for amplification of the first RF input signal FRFI to the RF PA circuitry **30**. The RF PA circuitry **30** may receive and amplify the second RF input signal SRFI to provide a second RF output signal SRFO. The envelope power supply signal EPS may provide power for amplification of the second RF output signal SRFO to the RF PA circuitry **30**. Certain configurations of the RF PA circuitry **30** may be based on the PA configuration control signal PCC. As a result, the RF modulation and control circuitry **28** may control such configurations of the RF PA circuitry **30**.

FIG. **4** shows the RF communications system **26** according to an additional embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **4** is similar to the RF communications system **26** illustrated in FIG. **3**, except in the RF communications system **26** illustrated in FIG. **4**, the RF PA circuitry **30** does not provide the first RF output signal FRFO and the second RF output signal

SRFO. Instead, the RF PA circuitry **30** may provide one of a first alpha RF transmit signal FATX, a second alpha RF transmit signal SATX, and up to and including a P^{TH} alpha RF transmit signal PATX based on receiving and amplifying the first RF input signal FRFI. Similarly, the RF PA circuitry **30** may provide one of a first beta RF transmit signal FBTX, a second beta RF transmit signal SBTX, and up to and including a Q^{TH} beta RF transmit signal QBTX based on receiving and amplifying the second RF input signal SRFI. The one of the transmit signals FATX, SATX, PATX, FBTX, SBTX, QBTX that is selected may be based on the PA configuration control signal PCC. Additionally, the RF modulation and control circuitry **28** may provide a DC configuration control signal DCC to the DC-DC converter **32**. Certain configurations of the DC-DC converter **32** may be based on the DC configuration control signal DCC.

FIG. **5** shows the RF communications system **26** according to another embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **5** shows details of the RF modulation and control circuitry **28** and the RF PA circuitry **30** illustrated in FIG. **4**. Additionally, the RF communications system **26** illustrated in FIG. **5** further includes transceiver circuitry **34**, front-end aggregation circuitry **36**, and the antenna **18**. The transceiver circuitry **34** includes down-conversion circuitry **38**, baseband processing circuitry **40**, and the RF modulation and control circuitry **28**, which includes control circuitry **42** and RF modulation circuitry **44**. The RF PA circuitry **30** includes a first transmit path **46** and a second transmit path **48**. The first transmit path **46** includes a first RF PA **50** and alpha switching circuitry **52**. The second transmit path **48** includes a second RF PA **54** and beta switching circuitry **56**. The front-end aggregation circuitry **36** is coupled to the antenna **18**. The control circuitry **42** provides the aggregation control signal ACS to the front-end aggregation circuitry **36**. Configuration of the front-end aggregation circuitry **36** may be based on the aggregation control signal ACS. As such, configuration of the front-end aggregation circuitry **36** may be controlled by the control circuitry **42** via the aggregation control signal ACS.

The control circuitry **42** provides the envelope control signal ECS and the DC configuration control signal DCC to the DC-DC converter **32**. Further, the control circuitry **42** provides the PA configuration control signal PCC to the RF PA circuitry **30**. As such, the control circuitry **42** may control configuration of the RF PA circuitry **30** via the PA configuration control signal PCC and may control a magnitude of the envelope power supply signal EPS via the envelope control signal ECS. The control circuitry **42** may select one of multiple communications modes, which may include a first half-duplex transmit mode, a first half-duplex receive mode, a second half-duplex transmit mode, a second half-duplex receive mode, a first full-duplex mode, a second full-duplex mode, at least one linear mode, at least one non-linear mode, multiple RF modulation modes, or any combination thereof. Further, the control circuitry **42** may select one of multiple frequency bands. The control circuitry **42** may provide the aggregation control signal ACS to the front-end aggregation circuitry **36** based on the selected mode and the selected frequency band. The front-end aggregation circuitry **36** may include various RF components, including RF switches; RF filters, such as bandpass filters, harmonic filters, and duplexers; RF amplifiers, such as low noise amplifiers (LNAs); impedance matching circuitry; the like; or any combination thereof. In this regard, routing of RF receive signals and RF transmit signals through the RF components may be based on the selected mode and the selected frequency band as directed by the aggregation control signal ACS.

The down-conversion circuitry **38** may receive the first RF receive signal FRX, the second RF receive signal SRX, and up to and including the M^{TH} RF receive signal MRX from the antenna **18** via the front-end aggregation circuitry **36**. Each of the RF receive signals FRX, SRX, MRX may be associated with at least one selected mode, at least one selected frequency band, or both. The down-conversion circuitry **38** may down-convert any of the RF receive signals FRX, SRX, MRX to baseband receive signals, which may be forwarded to the baseband processing circuitry **40** for processing. The baseband processing circuitry **40** may provide baseband transmit signals to the RF modulation circuitry **44**, which may RF modulate the baseband transmit signals to provide the first RF input signal FRFI or the second RF input signal SRFI to the first RF PA **50** or the second RF PA **54**, respectively, depending on the selected communications mode.

The first RF PA **50** may receive and amplify the first RF input signal FRFI to provide the first RF output signal FRFO to the alpha switching circuitry **52**. Similarly, the second RF PA **54** may receive and amplify the second RF input signal SRFI to provide the second RF output signal SRFO to the beta switching circuitry **56**. The first RF PA **50** and the second RF PA **54** may receive the envelope power supply signal EPS, which may provide power for amplification of the first RF input signal FRFI and the second RF input signal SRFI, respectively. The alpha switching circuitry **52** may forward the first RF output signal FRFO to provide one of the alpha transmit signals FATX, SATX, PATX to the antenna **18** via the front-end aggregation circuitry **36**, depending on the selected communications mode based on the PA configuration control signal PCC. Similarly, the beta switching circuitry **56** may forward the second RF output signal SRFO to provide one of the beta transmit signals FBTX, SBTX, QBTX to the antenna **18** via the front-end aggregation circuitry **36**, depending on the selected communications mode based on the PA configuration control signal PCC.

FIG. **6** shows the RF communications system **26** according to a further embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **6** is similar to the RF communications system **26** illustrated in FIG. **5**, except in the RF communications system **26** illustrated in FIG. **6**, the transceiver circuitry **34** includes a control circuitry digital communications interface (DCI) **58**, the RF PA circuitry **30** includes a PA-DCI **60**, the DC-DC converter **32** includes a DC-DC converter DCI **62**, and the front-end aggregation circuitry **36** includes an aggregation circuitry DCI **64**. The front-end aggregation circuitry **36** includes an antenna port AP, which is coupled to the antenna **18**. In one embodiment of the RF communications system **26**, the antenna port AP is directly coupled to the antenna **18**. In one embodiment of the RF communications system **26**, the front-end aggregation circuitry **36** is coupled between the alpha switching circuitry **52** and the antenna port AP. Further, the front-end aggregation circuitry **36** is coupled between the beta switching circuitry **56** and the antenna port AP. The alpha switching circuitry **52** may be multi-mode multi-band alpha switching circuitry and the beta switching circuitry **56** may be multi-mode multi-band beta switching circuitry.

The DCIs **58**, **60**, **62**, **64** are coupled to one another using a digital communications bus **66**. In the digital communications bus **66** illustrated in FIG. **6**, the digital communications bus **66** is a uni-directional bus in which the control circuitry DCI **58** may communicate information to the PA-DCI **60**, the DC-DC converter DCI **62**, the aggregation circuitry DCI **64**, or any combination thereof. As such, the control circuitry **42** may provide the envelope control signal ECS and the DC configuration control signal DCC via the control circuitry

DCI **58** to the DC-DC converter **32** via the DC-DC converter DCI **62**. Similarly, the control circuitry **42** may provide the aggregation control signal ACS via the control circuitry DCI **58** to the front-end aggregation circuitry **36** via the aggregation circuitry DCI **64**. Additionally, the control circuitry **42** may provide the PA configuration control signal PCC via the control circuitry DCI **58** to the RF PA circuitry **30** via the PA-DCI **60**.

FIG. **7** shows the RF communications system **26** according to one embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **7** is similar to the RF communications system **26** illustrated in FIG. **6**, except in the RF communications system **26** illustrated in FIG. **7**, the digital communications bus **66** is a bi-directional bus and each of the DCIs **58**, **60**, **62**, **64** is capable of receiving or transmitting information. In alternate embodiments of the RF communications system **26**, any or all of the DCIs **58**, **60**, **62**, **64** may be uni-directional and any or all of the DCIs **58**, **60**, **62**, **64** may be bi-directional.

FIG. **8** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to one embodiment of the RF PA circuitry **30**. Specifically, FIG. **8** shows details of the alpha switching circuitry **52** and the beta switching circuitry **56** according to one embodiment of the alpha switching circuitry **52** and the beta switching circuitry **56**. The alpha switching circuitry **52** includes an alpha RF switch **68** and a first alpha harmonic filter **70**. The beta switching circuitry **56** includes a beta RF switch **72** and a first beta harmonic filter **74**. Configuration of the alpha RF switch **68** and the beta RF switch **72** may be based on the PA configuration control signal PCC. In one communications mode, such as an alpha half-duplex transmit mode, an alpha saturated mode, or an alpha non-linear mode, the alpha RF switch **68** is configured to forward the first RF output signal FRFO to provide the first alpha RF transmit signal FATX via the first alpha harmonic filter **70**. In another communications mode, such as an alpha full-duplex mode or an alpha linear mode, the alpha RF switch **68** is configured to forward the first RF output signal FRFO to provide any of the second alpha RF transmit signal SATX through the P^{TH} alpha RF transmit signal PATX. When a specific RF band is selected, the alpha RF switch **68** may be configured to provide a corresponding selected one of the second alpha RF transmit signal SATX through the P^{TH} alpha RF transmit signal PATX.

In one communications mode, such as a beta half-duplex transmit mode, a beta saturated mode, or a beta non-linear mode, the beta RF switch **72** is configured to forward the second RF output signal SRFO to provide the first beta RF transmit signal FBTX via the first beta harmonic filter **74**. In another communications mode, such as a beta full-duplex mode or a beta linear mode, the beta RF switch **72** is configured to forward the second RF output signal SRFO to provide any of the second beta RF transmit signal SBTX through the Q^{TH} beta RF transmit signal QBTX. When a specific RF band is selected, beta RF switch **72** may be configured to provide a corresponding selected one of the second beta RF transmit signal SBTX through the Q^{TH} beta RF transmit signal QBTX. The first alpha harmonic filter **70** may be used to filter out harmonics of an RF carrier in the first RF output signal FRFO. The first beta harmonic filter **74** may be used to filter out harmonics of an RF carrier in the second RF output signal SRFO.

FIG. **9** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to an alternate embodiment of the RF PA circuitry **30**. Specifically, FIG. **9** shows details of the alpha switching circuitry **52** and the beta switching circuitry **56** according to an alternate embodiment of the alpha switching circuitry **52** and the beta switching circuitry **56**. The alpha switching circuitry **52** includes the alpha RF switch **68**, the first alpha harmonic filter **70**, and a second alpha harmonic filter **76**. The beta switching circuitry **56** includes the beta RF switch **72**, the first beta harmonic filter **74**, and a second beta harmonic filter **78**. Configuration of the alpha RF switch **68** and the beta RF switch **72** may be based on the PA configuration control signal PCC. In one communications mode, such as a first alpha half-duplex transmit mode, a first alpha saturated mode, or a first alpha non-linear mode, the alpha RF switch **68** is configured to forward the first RF output signal FRFO to provide the first alpha RF transmit signal FATX via the first alpha harmonic filter **70**. In another communications mode, such as a second alpha half-duplex transmit mode, a second alpha saturated mode, or a second alpha non-linear mode, the alpha RF switch **68** is configured to forward the first RF output signal FRFO to provide the second alpha RF transmit signal SATX via the second alpha harmonic filter **76**. In an alternate communications mode, such as an alpha full-duplex mode or an alpha linear mode, the alpha RF switch **68** is configured to forward the first RF output signal FRFO to provide any of a third alpha RF transmit signal TATX through the P^{TH} alpha RF transmit signal PATX. When a specific RF band is selected, the alpha RF switch **68** may be configured to provide a corresponding selected one of the third alpha RF transmit signal TATX through the P^{TH} alpha RF transmit signal PATX.

In one communications mode, such as a first beta half-duplex transmit mode, a first beta saturated mode, or a first beta non-linear mode, the beta RF switch **72** is configured to forward the second RF output signal SRFO to provide the first beta RF transmit signal FBTX via the first beta harmonic filter **74**. In another communications mode, such as a second beta half-duplex transmit mode, a second beta saturated mode, or a second beta non-linear mode, the beta RF switch **72** is configured to forward the second RF output signal SRFO to provide the second beta RF transmit signal SBTX via the second beta harmonic filter **78**. In an alternate communications mode, such as a beta full-duplex mode or a beta linear mode, the beta RF switch **72** is configured to forward the second RF output signal SRFO to provide any of a third beta RF transmit signal TBTX through the Q^{TH} beta RF transmit signal QBTX. When a specific RF band is selected, the beta RF switch **72** may be configured to provide a corresponding selected one of the third beta RF transmit signal TBTX through the Q^{TH} beta RF transmit signal QBTX. The first alpha harmonic filter **70** or the second alpha harmonic filter **76** may be used to filter out harmonics of an RF carrier in the first RF output signal FRFO. The first beta harmonic filter **74** or the second beta harmonic filter **78** may be used to filter out harmonics of an RF carrier in the second RF output signal SRFO.

FIG. **10** shows the RF communications system **26** according to one embodiment of the RF communications system **26**. The RF communications system **26** shown in FIG. **10** is similar to the RF communications system **26** shown in FIG. **4**, except the RF communications system **26** illustrated in FIG. **10** further includes a DC power supply **80** and the DC configuration control signal DCC is omitted. Additionally, details of the DC-DC converter **32** are shown according to one embodiment of the DC-DC converter **32**. The DC-DC converter **32** includes first power filtering circuitry **82**, a charge pump buck converter **84**, a buck converter **86**, second power filtering circuitry **88**, a first inductive element L**1**, and a second inductive element L**2**. The DC power supply **80** provides a DC power supply signal DCPS to the charge pump buck converter **84**, the buck converter **86**, and the second power filtering circuitry **88**. In one embodiment of the DC power supply **80**, the DC power supply **80** is a battery.

The second power filtering circuitry **88** is coupled to the RF PA circuitry **30** and to the DC power supply **80**. The charge pump buck converter **84** is coupled to the DC power supply **80**. The first inductive element L**1** is coupled between the charge pump buck converter **84** and the first power filtering circuitry **82**. The buck converter **86** is coupled to the DC power supply **80**. The second inductive element L**2** is coupled between the buck converter **86** and the first power filtering circuitry **82**. The first power filtering circuitry **82** is coupled to the RF PA circuitry **30**. One end of the first inductive element L**1** is coupled to one end of the second inductive element L**2** at the first power filtering circuitry **82**.

In one embodiment of the DC-DC converter **32**, the DC-DC converter **32** operates in one of multiple converter operating modes, which include a first converter operating mode, a second converter operating mode, and a third converter operating mode. In an alternate embodiment of the DC-DC converter **32**, the DC-DC converter **32** operates in one of the first converter operating mode and the second converter operating mode. In the first converter operating mode, the charge pump buck converter **84** is active, such that the envelope power supply signal EPS is based on the DC power supply signal DCPS via the charge pump buck converter **84**, and the first inductive element L**1**. In the first converter operating mode, the buck converter **86** is inactive and does not contribute to the envelope power supply signal EPS. In the second converter operating mode, the buck converter **86** is active, such that the envelope power supply signal EPS is based on the DC power supply signal DCPS via the buck converter **86** and the second inductive element L**2**. In the second converter operating mode, the charge pump buck converter **84** is inactive, such that the charge pump buck converter **84** does not contribute to the envelope power supply signal EPS. In the third converter operating mode, the charge pump buck converter **84** and the buck converter **86** are active, such that either the charge pump buck converter **84**; the buck converter **86**; or both may contribute to the envelope power supply signal EPS. As such, in the third converter operating mode, the envelope power supply signal EPS is based on the DC power supply signal DCPS either via the charge pump buck converter **84**, and the first inductive element L**1**; via the buck converter **86** and the second inductive element L**2**; or both.

The second power filtering circuitry **88** filters the DC power supply signal DCPS to provide the bias power supply signal BPS. The second power filtering circuitry **88** may function as a lowpass filter by removing ripple, noise, and the like from the DC power supply signal DCPS to provide the bias power supply signal BPS. As such, in one embodiment of the DC-DC converter **32**, the bias power supply signal BPS is based on the DC power supply signal DCPS.

In the first converter operating mode or the third converter operating mode, the charge pump buck converter **84** may receive, charge pump, and buck convert the DC power supply signal DCPS to provide a first buck output signal FBO to the first inductive element L**1**. As such, in one embodiment of the charge pump buck converter **84**, the first buck output signal FBO is based on the DC power supply signal DCPS. Further, the first inductive element L**1** may function as a first energy transfer element of the charge pump buck converter **84** to transfer energy via the first buck output signal FBO to the first power filtering circuitry **82**. In the first converter operating mode or the third converter operating mode, the first inductive element L**1** and the first power filtering circuitry **82** may receive and filter the first buck output signal FBO to provide the envelope power supply signal EPS. The charge pump buck converter **84** may regulate the envelope power supply signal EPS by controlling the first buck output signal FBO based on a setpoint of the envelope power supply signal EPS provided by the envelope control signal ECS.

In the second converter operating mode or the third converter operating mode, the buck converter **86** may receive and buck convert the DC power supply signal DCPS to provide a second buck output signal SBO to the second inductive element L**2**. As such, in one embodiment of the buck converter **86**, the second buck output signal SBO is based on the DC power supply signal DCPS. Further, the second inductive element L**2** may function as a second energy transfer element of the buck converter **86** to transfer energy via the first power filtering circuitry **82** to the first power filtering circuitry **82**. In the second converter operating mode or the third converter operating mode, the second inductive element L**2** and the first power filtering circuitry **82** may receive and filter the second buck output signal SBO to provide the envelope power supply signal EPS. The buck converter **86** may regulate the envelope power supply signal EPS by controlling the second buck output signal SBO based on a setpoint of the envelope power supply signal EPS provided by the envelope control signal ECS.

In one embodiment of the charge pump buck converter **84**, the charge pump buck converter **84** operates in one of multiple pump buck operating modes. During a pump buck pump-up operating mode of the charge pump buck converter **84**, the charge pump buck converter **84** pumps-up the DC power supply signal DCPS to provide an internal signal (not shown), such that a voltage of the internal signal is greater than a voltage of the DC power supply signal DCPS. In an alternate embodiment of the charge pump buck converter **84**, during the pump buck pump-up operating mode, a voltage of the envelope power supply signal EPS is greater than the voltage of the DC power supply signal DCPS. During a pump buck pump-down operating mode of the charge pump buck converter **84**, the charge pump buck converter **84** pumps-down the DC power supply signal DCPS to provide the internal signal, such that a voltage of the internal signal is less than a voltage of the DC power supply signal DCPS. In an alternate embodiment of the charge pump buck converter **84**, during the pump buck pump-down operating mode, the voltage of the envelope power supply signal EPS is less than the voltage of the DC power supply signal DCPS. During a pump buck pump-even operating mode of the charge pump buck converter **84**, the charge pump buck converter **84** pumps the DC power supply signal DCPS to the internal signal, such that a voltage of the internal signal is about equal to a voltage of the DC power supply signal DCPS. One embodiment of the DC-DC converter **32** includes a pump buck bypass operating mode of the charge pump buck converter **84**, such that during the pump buck bypass operating mode, the charge pump buck converter **84** by-passes charge pump circuitry (not shown) using by-pass circuitry (not shown) to forward the DC power supply signal DCPS to provide the internal signal, such that a voltage of the internal is about equal to a voltage of the DC power supply signal DCPS.

In one embodiment of the charge pump buck converter **84**, the pump buck operating modes include the pump buck pump-up operating mode, the pump buck pump-down operating mode, the pump buck pump-even operating mode, and the pump buck bypass operating mode. In an alternate embodiment of the charge pump buck converter **84**, the pump buck pump-even operating mode is omitted. In an additional embodiment of the charge pump buck converter **84**, the pump buck bypass operating mode is omitted. In another embodiment of the charge pump buck converter **84**, the pump buck pump-down operating mode is omitted. In a further embodiment of the charge pump buck converter **84**, any or all of the pump buck pump-up operating mode, the pump buck pump-down operating mode, the pump buck pump-even operating mode, and the pump buck bypass operating mode are omitted. In a supplemental embodiment of the charge pump buck converter **84**, the charge pump buck converter **84** operates in only the pump buck pump-up operating mode. In an additional embodiment of the charge pump buck converter **84**, the charge pump buck converter **84** operates in one of the pump buck pump-up operating mode and at least one other pump buck operating mode of the charge pump buck converter **84**. The at least one other pump buck operating mode of the charge pump buck converter **84** may include any or all of the pump buck pump-up operating mode, the pump buck pump-down operating mode, the pump buck pump-even operating mode, and the pump buck bypass operating mode.

FIG. **11** shows the RF communications system **26** according to an alternate embodiment of the RF communications system **26**. The RF communications system **26** illustrated in FIG. **11** is similar to the RF communications system **26** illustrated in FIG. **10**, except in the RF communications system **26** illustrated in FIG. **11**, the DC-DC converter **32** further includes DC-DC control circuitry **90** and a charge pump **92**, and omits the second inductive element L2. Instead of the second power filtering circuitry **88** being coupled to the DC power supply **80** as shown in FIG. **10**, the charge pump **92** is coupled to the DC power supply **80**, such that the charge pump **92** is coupled between the DC power supply **80** and the second power filtering circuitry **88**. Additionally, the RF modulation and control circuitry **28** provides the DC configuration control signal DCC and the envelope control signal ECS to the DC-DC control circuitry **90**.

The DC-DC control circuitry **90** provides a charge pump buck control signal CPBS to the charge pump buck converter **84**, provides a buck control signal BCS to the buck converter **86**, and provides a charge pump control signal CPS to the charge pump **92**. The charge pump buck control signal CPBS, the buck control signal BCS, or both may indicate which converter operating mode is selected. Further, the charge pump buck control signal CPBS, the buck control signal BCS, or both may provide the setpoint of the envelope power supply signal EPS as provided by the envelope control signal ECS. The charge pump buck control signal CPBS may indicate which pump buck operating mode is selected.

In one embodiment of the DC-DC converter **32**, selection of the converter operating mode is made by the DC-DC control circuitry **90**. In an alternate embodiment of the DC-DC converter **32**, selection of the converter operating mode is made by the RF modulation and control circuitry **28** and may be communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In an additional embodiment of the DC-DC converter **32**, selection of the converter operating mode is made by the control circuitry **42** (FIG. **5**) and may be communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In general, selection of the converter operating mode is made by control circuitry, which may be any of the DC-DC control circuitry **90**, the RF modulation and control circuitry **28**, and the control circuitry **42** (FIG. **5**).

In one embodiment of the DC-DC converter **32**, selection of the pump buck operating mode is made by the DC-DC control circuitry **90**. In an alternate embodiment of the DC-DC converter **32**, selection of the pump buck operating mode is made by the RF modulation and control circuitry **28** and communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In an additional embodiment of the DC-DC converter **32**, selection of the pump buck operating mode is made by the control circuitry **42** (FIG. **5**) and communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In general, selection of the pump buck operating mode is made by control circuitry, which may be any of the DC-DC control circuitry **90**, the RF modulation and control circuitry **28**, and the control circuitry **42** (FIG. **5**). As such, the control circuitry may select one of the pump buck pump-up operating mode and at least one other pump buck operating mode of the charge pump buck converter **84**. The at least one other pump buck operating mode of the charge pump buck converter **84** may include any or all of the pump buck pump-down operating mode, the pump buck pump-even operating mode, and the pump buck bypass operating mode.

The charge pump **92** may operate in one of multiple bias supply pump operating modes. During a bias supply pump-up operating mode of the charge pump **92**, the charge pump **92** receives and pumps-up the DC power supply signal DCPS to provide the bias power supply signal BPS, such that a voltage of the bias power supply signal BPS is greater than a voltage of the DC power supply signal DCPS. During a bias supply pump-down operating mode of the charge pump **92**, the charge pump **92** pumps-down the DC power supply signal DCPS to provide the bias power supply signal BPS, such that a voltage of the bias power supply signal BPS is less than a voltage of the DC power supply signal DCPS. During a bias supply pump-even operating mode of the charge pump **92**, the charge pump **92** pumps the DC power supply signal DCPS to provide the bias power supply signal BPS, such that a voltage of the bias power supply signal BPS is about equal to a voltage of the DC power supply signal DCPS. One embodiment of the DC-DC converter **32** includes a bias supply bypass operating mode of the charge pump **92**, such that during the bias supply bypass operating mode, the charge pump **92** by-passes charge pump circuitry (not shown) using by-pass circuitry (not shown) to forward the DC power supply signal DCPS to provide the bias power supply signal BPS, such that a voltage of the bias power supply signal BPS is about equal to a voltage of the DC power supply signal DCPS. The charge pump control signal CPS may indicate which bias supply pump operating mode is selected.

In one embodiment of the charge pump **92**, the bias supply pump operating modes include the bias supply pump-up operating mode, the bias supply pump-down operating mode, the bias supply pump-even operating mode, and the bias supply bypass operating mode. In an alternate embodiment of the charge pump **92**, the bias supply pump-even operating mode is omitted. In an additional embodiment of the charge pump **92**, the bias supply bypass operating mode is omitted. In another embodiment of the charge pump **92**, the bias supply pump-down operating mode is omitted. In a further embodiment of the charge pump **92**, any or all of the bias supply pump-up operating mode, the bias supply pump-down operating mode, the bias supply pump-even operating mode, and the bias supply bypass operating mode are omitted. In a supplemental embodiment of the charge pump **92**, the charge pump **92** operates in only the bias supply pump-up operating mode. In an additional embodiment of the charge pump **92**, the charge pump **92** operates in the bias supply pump-up operating mode and at least one other operating mode of the charge pump **92**, which may include any or all of the bias supply pump-down operating mode, the bias supply pump-even operating mode, and the bias supply bypass operating mode.

In one embodiment of the DC-DC converter **32**, selection of the bias supply pump operating mode is made by the

DC-DC control circuitry **90**. In an alternate embodiment of the DC-DC converter **32**, selection of the bias supply pump operating mode is made by the RF modulation and control circuitry **28** and communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In an additional embodiment of the DC-DC converter **32**, selection of the bias supply pump operating mode is made by the control circuitry **42** (FIG. **5**) and communicated to the DC-DC converter **32** via the DC configuration control signal DCC. In general, selection of the bias supply pump operating mode is made by control circuitry, which may be any of the DC-DC control circuitry **90**, the RF modulation and control circuitry **28**, and the control circuitry **42** (FIG. **5**). As such, the control circuitry may select one of the bias supply pump-up operating mode and at least one other bias supply operating mode. The at least one other bias supply operating mode may include any or all of the bias supply pump-down operating mode, the bias supply pump-even operating mode, and the bias supply bypass operating mode.

The second power filtering circuitry **88** filters the bias power supply signal BPS. The second power filtering circuitry **88** may function as a lowpass filter by removing ripple, noise, and the like to provide the bias power supply signal BPS. As such, in one embodiment of the DC-DC converter **32**, the bias power supply signal BPS is based on the DC power supply signal DCPS.

Regarding omission of the second inductive element L**2**, instead of the second inductive element L**2** coupled between the buck converter **86** and the first power filtering circuitry **82** as shown in FIG. **10**, one end of the first inductive element L**1** is coupled to both the charge pump buck converter **84** and the buck converter **86**. As such, in the second converter operating mode or the third converter operating mode, the buck converter **86** may receive and buck convert the DC power supply signal DCPS to provide the second buck output signal SBO to the first inductive element L**1**. As such, in one embodiment of the charge pump buck converter **84**, the second buck output signal SBO is based on the DC power supply signal DCPS. Further, the first inductive element L**1** may function as a first energy transfer element of the buck converter **86** to transfer energy via the second buck output signal SBO to the first power filtering circuitry **82**. In the first converter operating mode, the second converter operating mode, or the third converter operating mode, the first inductive element L**1** and the first power filtering circuitry **82** receive and filter the first buck output signal FBO, the second buck output signal SBO, or both to provide the envelope power supply signal EPS.

FIG. **12** shows details of the DC-DC converter **32** illustrated in FIG. **11** according to an alternate embodiment of the DC-DC converter **32**. The DC-DC converter **32** illustrated in FIG. **12** is similar to the DC-DC converter **32** illustrated in FIG. **10**, except the DC-DC converter **32** illustrated in FIG. **12** shows details of the first power filtering circuitry **82** and the second power filtering circuitry **88**. Further, the DC-DC converter **32** illustrated in FIG. **12** includes the DC-DC control circuitry **90** and the charge pump **92** as shown in FIG. **11**.

The first power filtering circuitry **82** includes a first capacitive element C**1**, a second capacitive element C**2**, and a third inductive element L**3**. The first capacitive element C**1** is coupled between one end of the third inductive element L**3** and a ground. The second capacitive element C**2** is coupled between an opposite end of the third inductive element L**3** and ground. The one end of the third inductive element L**3** is coupled to one end of the first inductive element L**1**. Further, the one end of the third inductive element L**3** is coupled to one end of the second inductive element L**2**. In an additional embodiment of the DC-DC converter **32**, the second inductive element L**2** is omitted. The opposite end of the third inductive element L**3** is coupled to the RF PA circuitry **30**. As such, the opposite end of the third inductive element L**3** and one end of the second capacitive element C**2** provide the envelope power supply signal EPS. In an alternate embodiment of the first power filtering circuitry **82**, the third inductive element L**3**, the second capacitive element C**2**, or both are omitted.

FIG. **13** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to one embodiment of the RF PA circuitry **30**. The RF PA circuitry **30** illustrated in FIG. **13** is similar to the RF PA circuitry **30** illustrated in FIG. **5**, except the RF PA circuitry **30** illustrated in FIG. **13** further includes PA control circuitry **94**, PA bias circuitry **96**, and switch driver circuitry **98**. The PA bias circuitry **96** is coupled between the PA control circuitry **94** and the RF PAs **50**, **54**. The switch driver circuitry **98** is coupled between the PA control circuitry **94** and the switching circuitry **52**, **56**. The PA control circuitry **94** receives the PA configuration control signal PCC, provides a bias configuration control signal BCC to the PA bias circuitry **96** based on the PA configuration control signal PCC, and provides a switch configuration control signal SCC to the switch driver circuitry **98** based on the PA configuration control signal PCC. The switch driver circuitry **98** provides any needed drive signals to configure the alpha switching circuitry **52** and the beta switching circuitry **56**.

The PA bias circuitry **96** receives the bias power supply signal BPS and the bias configuration control signal BCC. The PA bias circuitry **96** provides a first driver bias signal FDB and a first final bias signal FFB to the first RF PA **50** based on the bias power supply signal BPS and the bias configuration control signal BCC. The PA bias circuitry **96** provides a second driver bias signal SDB and a second final bias signal SFB to the second RF PA **54** based on the bias power supply signal BPS and the bias configuration control signal BCC. The bias power supply signal BPS provides the power necessary to generate the bias signals FDB, FFB, SDB, SFB. A selected magnitude of each of the bias signals FDB, FFB, SDB, SFB is provided by the PA bias circuitry **96**. In one embodiment of the RF PA circuitry **30**, the PA control circuitry **94** selects the magnitude of any or all of the bias signals FDB, FFB, SDB, SFB and communicates the magnitude selections to the PA bias circuitry **96** via the bias configuration control signal BCC. The magnitude selections by the PA control circuitry **94** may be based on the PA configuration control signal PCC. In an alternate embodiment of the RF PA circuitry **30**, the control circuitry **42** (FIG. **5**) selects the magnitude of any or all of the bias signals FDB, FFB, SDB, SFB and communicates the magnitude selections to the PA bias circuitry **96** via the PA control circuitry **94**.

In one embodiment of the RF PA circuitry **30**, the RF PA circuitry **30** operates in one of a first PA operating mode and a second PA operating mode. During the first PA operating mode, the first transmit path **46** is enabled and the second transmit path **48** is disabled. During the second PA operating mode, the first transmit path **46** is disabled and the second transmit path **48** is enabled. In one embodiment of the first RF PA **50** and the second RF PA **54**, during the second PA operating mode, the first RF PA **50** is disabled, and during the first PA operating mode, the second RF PA **54** is disabled. In one embodiment of the alpha switching circuitry **52** and the beta switching circuitry **56**, during the second PA operating mode, the alpha switching circuitry **52** is disabled, and during the first PA operating mode, the beta switching circuitry **56** is disabled.

In one embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via the first driver bias signal FDB. In an alternate embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via the first final bias signal FFB. In an additional embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via both the first driver bias signal FDB and the first final bias signal FFB. In one embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via the second driver bias signal SDB. In an alternate embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via the second final bias signal SFB. In an additional embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via both the second driver bias signal SDB and the second final bias signal SFB.

In one embodiment of the RF PA circuitry **30**, the PA control circuitry **94** selects the one of the first PA operating mode and the second PA operating mode. As such, the PA control circuitry **94** may control any or all of the bias signals FDB, FFB, SDB, SFB via the bias configuration control signal BCC based on the PA operating mode selection. Further, the PA control circuitry **94** may control the switching circuitry **52**, **56** via the switch configuration control signal SCC based on the PA operating mode selection. The PA operating mode selection may be based on the PA configuration control signal PCC. In an alternate embodiment of the RF PA circuitry **30**, the control circuitry **42** (FIG. **5**) selects the one of the first PA operating mode and the second PA operating mode. As such, the control circuitry **42** (FIG. **5**) may indicate the operating mode selection to the PA control circuitry **94** via the PA configuration control signal PCC. In an additional embodiment of the RF PA circuitry **30**, the RF modulation and control circuitry **28** (FIG. **5**) selects the one of the first PA operating mode and the second PA operating mode. As such, the RF modulation and control circuitry **28** (FIG. **5**) may indicate the operating mode selection to the PA control circuitry **94** via the PA configuration control signal PCC. In general, selection of the PA operating mode is made by control circuitry, which may be any of the PA control circuitry **94**, the RF modulation and control circuitry **28** (FIG. **5**), and the control circuitry **42** (FIG. **5**).

FIG. **14** shows details of the RF PA circuitry **30** illustrated in FIG. **6** according to an alternate embodiment of the RF PA circuitry **30**. The RF PA circuitry **30** illustrated in FIG. **14** is similar to the RF PA circuitry **30** illustrated in FIG. **13**, except the RF PA circuitry **30** illustrated in FIG. **14** further includes the PA-DCI **60**, which is coupled to the PA control circuitry **94** and to the digital communications bus **66**. As such, the control circuitry **42** (FIG. **6**) may provide the PA configuration control signal PCC via the control circuitry DCI **58** (FIG. **6**) to the PA control circuitry **94** via the PA-DCI **60**.

FIG. **15** shows details of the first RF PA **50** and the second RF PA **54** illustrated in FIG. **13** according one embodiment of the first RF PA **50** and the second RF PA **54**. The first RF PA **50** includes a first non-quadrature PA path **100** and a first quadrature PA path **102**. The second RF PA **54** includes a second non-quadrature PA path **104** and a second quadrature PA path **106**. In one embodiment of the first RF PA **50**, the first quadrature PA path **102** is coupled between the first non-quadrature PA path **100** and the antenna port AP (FIG. **6**), which is coupled to the antenna **18** (FIG. **6**). In an alternate embodiment of the first RF PA **50**, the first non-quadrature PA path **100** is omitted, such that the first quadrature PA path **102** is coupled to the antenna port AP (FIG. **6**). The first quadrature PA path **102** may be coupled to the antenna port AP (FIG. **6**) via the alpha switching circuitry **52** (FIG. **6**) and the front-end aggregation circuitry **36** (FIG. **6**). The first non-quadrature PA path **100** may include any number of non-quadrature gain stages. The first quadrature PA path **102** may include any number of quadrature gain stages. In one embodiment of the second RF PA **54**, the second quadrature PA path **106** is coupled between the second non-quadrature PA path **104** and the antenna port AP (FIG. **6**). In an alternate embodiment of the second RF PA **54**, the second non-quadrature PA path **104** is omitted, such that the second quadrature PA path **106** is coupled to the antenna port AP (FIG. **6**). The second quadrature PA path **106** may be coupled to the antenna port AP (FIG. **6**) via the beta switching circuitry **56** (FIG. **6**) and the front-end aggregation circuitry **36** (FIG. **6**). The second non-quadrature PA path **104** may include any number of non-quadrature gain stages. The second quadrature PA path **106** may include any number of quadrature gain stages.

In one embodiment of the RF communications system **26**, the control circuitry **42** (FIG. **5**) selects one of multiple communications modes, which include a first PA operating mode and a second PA operating mode. During the first PA operating mode, the first PA paths **100**, **102** receive the envelope power supply signal EPS, which provides power for amplification. During the second PA operating mode, the second PA paths **104**, **106** receive the envelope power supply signal EPS, which provides power for amplification. During the first PA operating mode, the first non-quadrature PA path **100** receives the first driver bias signal FDB, which provides biasing to the first non-quadrature PA path **100**, and the first quadrature PA path **102** receives the first final bias signal FFB, which provides biasing to the first quadrature PA path **102**. During the second PA operating mode, the second non-quadrature PA path **104** receives the second driver bias signal SDB, which provides biasing to the second non-quadrature PA path **104**, and the second quadrature PA path **106** receives the second final bias signal SFB, which provides biasing to the second quadrature PA path **106**.

The first non-quadrature PA path **100** has a first single-ended output FSO and the first quadrature PA path **102** has a first single-ended input FSI. The first single-ended output FSO may be coupled to the first single-ended input FSI. In one embodiment of the first RF PA **50**, the first single-ended output FSO is directly coupled to the first single-ended input FSI. The second non-quadrature PA path **104** has a second single-ended output SSO and the second quadrature PA path **106** has a second single-ended input SSI. The second single-ended output SSO may be coupled to the second single-ended input SSI. In one embodiment of the second RF PA **54**, the second single-ended output SSO is directly coupled to the second single-ended input SSI.

During the first PA operating mode, the first RF PA **50** receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO, and the second RF PA **54** is disabled. During the second PA operating mode, the second RF PA **54** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO, and the first RF PA **50** is disabled. In one embodiment of the RF communications system **26**, the first RF input signal FRFI is a highband RF input signal and the second RF input signal SRFI is a lowband RF input signal. In one exemplary embodiment of the RF communications system **26**, a difference between a frequency of the highband RF input signal and a frequency of the lowband RF input signal is greater than about 500 megahertz, such that the frequency of the highband RF input signal is greater than the frequency of the lowband RF input signal. In an alternate exemplary embodiment of the RF communications system **26**, a ratio of a frequency of the highband RF input signal divided by a frequency of the lowband RF input signal is greater than about 1.5.

In one embodiment of the first RF PA **50**, during the first PA operating mode, the first non-quadrature PA path **100** receives and amplifies the first RF input signal FRFI to provide a first RF feeder output signal FFO to the first quadrature PA path **102** via the first single-ended output FSO. Further, during the first PA operating mode, the first quadrature PA path **102** receives and amplifies the first RF feeder output signal FFO via the first single-ended input FSI to provide the first RF output signal FRFO. In one embodiment of the second RF PA **54**, during the second PA operating mode, the second non-quadrature PA path **104** receives and amplifies the second RF input signal SRFI to provide a second RF feeder output signal SFO to the second quadrature PA path **106** via the second single-ended output SSO. Further, during the second PA operating mode, the second quadrature PA path **106** receives and amplifies the second RF feeder output signal SFO via the second single-ended input SSI to provide the second RF output signal SRFO.

Quadrature PA Architecture

A summary of quadrature PA architecture is presented, followed by a detailed description of the quadrature PA architecture according to one embodiment of the present disclosure. One embodiment of the RF communications system **26** (FIG. **6**) relates to a quadrature RF PA architecture that utilizes a single-ended interface to couple a non-quadrature PA path to a quadrature PA path, which may be coupled to the antenna port (FIG. **6**). The quadrature nature of the quadrature PA path may provide tolerance for changes in antenna loading conditions. An RF splitter in the quadrature PA path may present a relatively stable input impedance, which may be predominantly resistive, to the non-quadrature PA path over a wide frequency range, thereby substantially isolating the non-quadrature PA path from changes in the antenna loading conditions. Further, the input impedance may substantially establish a load line slope of a feeder PA stage in the non-quadrature PA path, thereby simplifying the quadrature RF PA architecture. One embodiment of the quadrature RF PA architecture uses two separate PA paths, either of which may incorporate a combined non-quadrature and quadrature PA architecture.

Due to the relatively stable input impedance, RF power measurements taken at the single-ended interface may provide high directivity and accuracy. Further, by combining the non-quadrature PA path and the quadrature PA path, gain stages may be eliminated and circuit topology may be simplified. In one embodiment of the RF splitter, the RF splitter is a quadrature hybrid coupler, which may include a pair of tightly coupled inductors. The input impedance may be based on inductances of the pair of tightly coupled inductors and parasitic capacitance between the inductors. As such, construction of the pair of tightly coupled inductors may be varied to select a specific parasitic capacitance to provide a specific input impedance. Further, the RF splitter may be integrated onto one semiconductor die with amplifying elements of the non-quadrature PA path, with amplifying elements of the quadrature PA path, or both, thereby reducing size and cost. Additionally, the quadrature PA path may have only a single quadrature amplifier stage to further simplify the design. In certain embodiments, using only the single quadrature amplifier stage provides adequate tolerance for changes in antenna loading conditions.

FIG. **16** shows details of the first non-quadrature PA path **100** and the second non-quadrature PA path **104** illustrated in FIG. **15** according to one embodiment of the first non-quadrature PA path **100** and the second non-quadrature PA path **104**.

The first non-quadrature PA path **100** includes a first input PA impedance matching circuit **108**, a first input PA stage **110**, a first feeder PA impedance matching circuit **112**, and a first feeder PA stage **114**, which provides the first single-ended output FSO. The first input PA stage **110** is coupled between the first input PA impedance matching circuit **108** and the first feeder PA impedance matching circuit **112**. The first feeder PA stage **114** is coupled between the first feeder PA impedance matching circuit **112** and the first quadrature PA path **102**. The first input PA impedance matching circuit **108** may provide at least an approximate impedance match between the RF modulation circuitry **44** (FIG. **5**) and the first input PA stage **110**. The first feeder PA impedance matching circuit **112** may provide at least an approximate impedance match between the first input PA stage **110** and the first feeder PA stage **114**. In alternate embodiments of the first non-quadrature PA path **100**, any or all of the first input PA impedance matching circuit **108**, the first input PA stage **110**, and the first feeder PA impedance matching circuit **112**, may be omitted.

During the first PA operating mode, the first input PA impedance matching circuit **108** receives and forwards the first RF input signal FRFI to the first input PA stage **110**. During the first PA operating mode, the first input PA stage **110** receives and amplifies the forwarded first RF input signal FRFI to provide a first RF feeder input signal FFI to the first feeder PA stage **114** via the first feeder PA impedance matching circuit **112**. During the first PA operating mode, the first feeder PA stage **114** receives and amplifies the first RF feeder input signal FFI to provide the first RF feeder output signal FFO via the first single-ended output FSO. The first feeder PA stage **114** may have a first output load line having a first load line slope. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first input PA stage **110** and to the first feeder PA stage **114**. During the first PA operating mode, the first driver bias signal FDB provides biasing to the first input PA stage **110** and the first feeder PA stage **114**.

The second non-quadrature PA path **104** includes a second input PA impedance matching circuit **116**, a second input PA stage **118**, a second feeder PA impedance matching circuit **120**, and a second feeder PA stage **122**, which provides the second single-ended output SSO. The second input PA stage **118** is coupled between the second input PA impedance matching circuit **116** and the second feeder PA impedance matching circuit **120**. The second feeder PA stage **122** is coupled between the second feeder PA impedance matching circuit **120** and the second quadrature PA path **106**. The second input PA impedance matching circuit **116** may provide at least an approximate impedance match between the RF modulation circuitry **44** (FIG. **5**) and the second input PA stage **118**. The second feeder PA impedance matching circuit **120** may provide at least an approximate impedance match between the second input PA stage **118** and the second feeder PA stage **122**. In alternate embodiments of the second non-quadrature PA path **104**, any or all of the second input PA impedance matching circuit **116**, the second input PA stage **118**, and the second feeder PA impedance matching circuit **120**, may be omitted.

During the second PA operating mode, the second input PA impedance matching circuit **116** receives and forwards the second RF input signal SRFI to the second input PA stage **118**. During the second PA operating mode, the second input PA stage **118** receives and amplifies the forwarded second RF input signal SRFI to provide a second RF feeder input signal SFI to the second feeder PA stage **122** via the second feeder PA impedance matching circuit **120**. During the second PA operating mode, the second feeder PA stage **122** receives and amplifies the second RF feeder input signal SFI to provide the second RF feeder output signal SFO via the second single-ended output SSO. The second feeder PA stage **122** may have a second output load line having a second load line slope. During the second PA operating mode, the envelope power supply signal EPS provides power for amplification to the second input PA stage **118** and to the second feeder PA stage **122**. During the second PA operating mode, the second driver bias signal SDB provides biasing to the second input PA stage **118** and the second feeder PA stage **122**.

FIG. **17** shows details of the first quadrature PA path **102** and the second quadrature PA path **106** illustrated in FIG. **15** according to one embodiment of the first quadrature PA path **102** and the second quadrature PA path **106**. The first quadrature PA path **102** includes a first quadrature RF splitter **124**, a first in-phase amplification path **126**, a first quadrature-phase amplification path **128**, and a first quadrature RF combiner **130**. The first quadrature RF splitter **124** has a first single-ended input FSI, a first in-phase output FIO, and a first quadrature-phase output FQO. The first quadrature RF combiner **130** has a first in-phase input FII, a first quadrature-phase input FQI, and a first quadrature combiner output FCO. The first single-ended output FSO is coupled to the first single-ended input FSI. In one embodiment of the first quadrature PA path **102**, the first single-ended output FSO is directly coupled to the first single-ended input FSI. The first in-phase amplification path **126** is coupled between the first in-phase output FIO and the first in-phase input FII. The first quadrature-phase amplification path **128** is coupled between the first quadrature-phase output FQO and the first quadrature-phase input FQI. The first quadrature combiner output FCO is coupled to the antenna port AP (FIG. **6**) via the alpha switching circuitry **52** (FIG. **6**) and the front-end aggregation circuitry **36** (FIG. **6**).

During the first PA operating mode, the first quadrature RF splitter **124** receives the first RF feeder output signal FFO via the first single-ended input FSI. Further, during the first PA operating mode, the first quadrature RF splitter **124** splits and phase-shifts the first RF feeder output signal FFO into a first in-phase RF input signal FIN and a first quadrature-phase RF input signal FQN, such that the first quadrature-phase RF input signal FQN is nominally phase-shifted from the first in-phase RF input signal FIN by about 90 degrees. The first quadrature RF splitter **124** has a first input impedance presented at the first single-ended input FSI. In one embodiment of the first quadrature RF splitter **124**, the first input impedance establishes the first load line slope. During the first PA operating mode, the first in-phase amplification path **126** receives and amplifies the first in-phase RF input signal FIN to provide the first in-phase RF output signal FIT. The first quadrature-phase amplification path **128** receives and amplifies the first quadrature-phase RF input signal FQN to provide the first quadrature-phase RF output signal FQT.

During the first PA operating mode, the first quadrature RF combiner **130** receives the first in-phase RF output signal FIT via the first in-phase input FII, and receives the first quadrature-phase RF output signal FQT via the first quadrature-phase input FQI. Further, the first quadrature RF combiner **130** phase-shifts and combines the first in-phase RF output signal FIT and the first quadrature-phase RF output signal FQT to provide the first RF output signal FRFO via the first quadrature combiner output FCO, such that the phase-shifted first in-phase RF output signal FIT and first quadrature-phase RF output signal FQT are about phase-aligned with one another before combining. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first in-phase amplification path **126** and the first quadrature-phase amplification path **128**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first in-phase amplification path **126** and the first quadrature-phase amplification path **128**.

The second quadrature PA path **106** includes a second quadrature RF splitter **132**, a second in-phase amplification path **134**, a second quadrature-phase amplification path **136**, and a second quadrature RF combiner **138**. The second quadrature RF splitter **132** has a second single-ended input SSI, a second in-phase output SIO, and a second quadrature-phase output SQO. The second quadrature RF combiner **138** has a second in-phase input SII, a second quadrature-phase input SQI, and a second quadrature combiner output SCO. The second single-ended output SSO is coupled to the second single-ended input SSI. In one embodiment of the second quadrature PA path **106**, the second single-ended output SSO is directly coupled to the second single-ended input SSI. The second in-phase amplification path **134** is coupled between the second in-phase output SIO and the second in-phase input SII. The second quadrature-phase amplification path **136** is coupled between the second quadrature-phase output SQO and the second quadrature-phase input SQI. The second quadrature combiner output SCO is coupled to the antenna port AP (FIG. **6**) via the alpha switching circuitry **52** (FIG. **6**) and the front-end aggregation circuitry **36** (FIG. **6**).

During the second PA operating mode, the second quadrature RF splitter **132** receives the second RF feeder output signal SFO via the second single-ended input SSI. Further, during the second PA operating mode, the second quadrature RF splitter **132** splits and phase-shifts the second RF feeder output signal SFO into a second in-phase RF input signal SIN and a second quadrature-phase RF input signal SQN, such that the second quadrature-phase RF input signal SQN is nominally phase-shifted from the second in-phase RF input signal SIN by about 90 degrees. The second quadrature RF splitter **132** has a second input impedance presented at the second single-ended input SSI. In one embodiment of the second quadrature RF splitter **132**, the second input impedance establishes the second load line slope. During the second PA operating mode, the second in-phase amplification path **134** receives and amplifies the second in-phase RF input signal SIN to provide the second in-phase RF output signal SIT. The second quadrature-phase amplification path **136** receives and amplifies the second quadrature-phase RF input signal SQN to provide the second quadrature-phase RF output signal SQT.

During the second PA operating mode, the second quadrature RF combiner **138** receives the second in-phase RF output signal SIT via the second in-phase input SII, and receives the second quadrature-phase RF output signal SQT via the second quadrature-phase input SQI. Further, the second quadrature RF combiner **138** phase-shifts and combines the second in-phase RF output signal SIT and the second quadrature-phase RF output signal SQT to provide the second RF output signal SRFO via the second quadrature combiner output SCO, such that the phase-shifted second in-phase RF output signal SIT and second quadrature-phase RF output signal SQT are about phase-aligned with one another before combining. During the second PA operating mode, the envelope power supply signal EPS provides power for amplification to the second in-phase amplification path **134** and the second quadrature-phase amplification path **136**. During the second PA operating mode, the second final bias signal SFB provides biasing to the second in-phase amplification path **134** and the second quadrature-phase amplification path **136**.

In one embodiment of the RF PA circuitry **30** (FIG. **13**), the second transmit path **48** (FIG. **13**) is omitted. As such, the first feeder PA stage **114** (FIG. **16**) is a feeder PA stage and the first single-ended output FSO (FIG. **16**) is a single-ended output. The first RF feeder input signal FFI (FIG. **16**) is an RF feeder input signal and the first RF feeder output signal FFO (FIG. **16**) is an RF feeder output signal. The feeder PA stage receives and amplifies the RF feeder input signal to provide the RF feeder output signal via the single-ended output. The feeder PA stage has an output load line having a load line slope. The first quadrature RF splitter **124** is a quadrature RF splitter and the first single-ended input FSI is a single-ended input. As such, the quadrature RF splitter has the single-ended input. In one embodiment of the first RF PA **50**, the single-ended output is directly coupled to the single-ended input.

In the embodiment in which the second transmit path **48** (FIG. **13**) is omitted, the first in-phase RF input signal FIN is an in-phase RF input signal and the first quadrature-phase RF input signal FQN is a quadrature-phase RF input signal. The quadrature RF splitter receives the RF feeder output signal via the single-ended input. Further, the quadrature RF splitter splits and phase-shifts the RF feeder output signal into the in-phase RF input signal and the quadrature-phase RF input signal, such that the quadrature-phase RF input signal is nominally phase-shifted from the in-phase RF input signal by about 90 degrees. The quadrature RF splitter has an input impedance presented at the single-ended input. The input impedance substantially establishes the load line slope. The first in-phase amplification path **126** is an in-phase amplification path and the first quadrature-phase amplification path **128** is a quadrature-phase amplification path. The first in-phase RF output signal FIT is an in-phase RF output signal and the first quadrature-phase RF output signal FQT is a quadrature-phase RF output signal. As such, the in-phase amplification path receives and amplifies the in-phase RF input signal to provide the in-phase RF output signal. The quadrature-phase amplification path receives and amplifies the quadrature-phase RF input signal to provide the quadrature-phase RF output signal.

In the embodiment in which the second transmit path **48** (FIG. **13**) is omitted, the first RF output signal FRFO is an RF output signal. As such, the quadrature RF combiner receives, phase-shifts, and combines the in-phase RF output signal and the quadrature-phase RF output signal to provide the RF output signal. In one embodiment of the quadrature RF splitter, the input impedance has resistance and reactance, such that the reactance is less than the resistance. In a first exemplary embodiment of the quadrature RF splitter, the resistance is greater than two times the reactance. In a second exemplary embodiment of the quadrature RF splitter, the resistance is greater than four times the reactance. In a third exemplary embodiment of the quadrature RF splitter, the resistance is greater than six times the reactance. In a fourth exemplary embodiment of the quadrature RF splitter, the resistance is greater than eight times the reactance. In a first exemplary embodiment of the quadrature RF splitter, the resistance is greater than ten times the reactance.

In alternate embodiments of the first quadrature PA path **102** and the second quadrature PA path **106**, any or all of the first quadrature RF splitter **124**, the first quadrature RF combiner **130**, the second quadrature RF splitter **132**, and the second quadrature RF combiner **138** may be any combination of quadrature RF couplers, quadrature hybrid RF couplers; Fisher couplers; lumped-element based RF couplers; transmission line based RF couplers; and combinations of phase-shifting circuitry and RF power couplers, such as phase-shifting circuitry and Wilkinson couplers; and the like. As such, any of the RF couplers listed above may be suitable to provide the first input impedance, the second input impedance, or both.

FIG. **18** shows details of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, the second in-phase amplification path **134**, and the second quadrature-phase amplification path **136** illustrated in FIG. **17** according to one embodiment of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, the second in-phase amplification path **134**, and the second quadrature-phase amplification path **136**. The first in-phase amplification path **126** includes a first in-phase driver PA impedance matching circuit **140**, a first in-phase driver PA stage **142**, a first in-phase final PA impedance matching circuit **144**, a first in-phase final PA stage **146**, and a first in-phase combiner impedance matching circuit **148**. The first in-phase driver PA impedance matching circuit **140** is coupled between the first in-phase output FIO and the first in-phase driver PA stage **142**. The first in-phase final PA impedance matching circuit **144** is coupled between the first in-phase driver PA stage **142** and the first in-phase final PA stage **146**. The first in-phase combiner impedance matching circuit **148** is coupled between the first in-phase final PA stage **146** and the first in-phase input FII.

The first in-phase driver PA impedance matching circuit **140** may provide at least an approximate impedance match between the first quadrature RF splitter **124** and the first in-phase driver PA stage **142**. The first in-phase final PA impedance matching circuit **144** may provide at least an approximate impedance match between the first in-phase driver PA stage **142** and the first in-phase final PA stage **146**. The first in-phase combiner impedance matching circuit **148** may provide at least an approximate impedance match between the first in-phase final PA stage **146** and the first quadrature RF combiner **130**.

During the first PA operating mode, the first in-phase driver PA impedance matching circuit **140** receives and forwards the first in-phase RF input signal FIN to the first in-phase driver PA stage **142**, which receives and amplifies the forwarded first in-phase RF input signal to provide an amplified first in-phase RF input signal to the first in-phase final PA stage **146** via the first in-phase final PA impedance matching circuit **144**. The first in-phase final PA stage **146** receives and amplifies the amplified first in-phase RF input signal to provide the first in-phase RF output signal FIT via the first in-phase combiner impedance matching circuit **148**. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first in-phase driver PA stage **142** and the first in-phase final PA stage **146**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first in-phase driver PA stage **142** and the first in-phase final PA stage **146**.

The first quadrature-phase amplification path **128** includes a first quadrature-phase driver PA impedance matching circuit **150**, a first quadrature-phase driver PA stage **152**, a first quadrature-phase final PA impedance matching circuit **154**, a first quadrature-phase final PA stage **156**, and a first quadrature-phase combiner impedance matching circuit **158**. The first quadrature-phase driver PA impedance matching circuit **150** is coupled between the first quadrature-phase output FQO and the first quadrature-phase driver PA stage **152**. The first quadrature-phase final PA impedance matching circuit **154** is coupled between the first quadrature-phase driver PA stage **152** and the first quadrature-phase final PA stage **156**. The first quadrature-phase combiner impedance matching circuit **158** is coupled between the first quadrature-phase final PA stage **156** and the first quadrature-phase input FQI.

The first quadrature-phase driver PA impedance matching circuit **150** may provide at least an approximate impedance match between the first quadrature RF splitter **124** and the first quadrature-phase driver PA stage **152**. The first quadrature-phase final PA impedance matching circuit **154** may provide at least an approximate impedance match between the first quadrature-phase driver PA stage **152** and the first quadrature-phase final PA stage **156**. The first quadrature-phase combiner impedance matching circuit **158** may provide at least an approximate impedance match between the first quadrature-phase final PA stage **156** and the first quadrature RF combiner **130**.

During the first PA operating mode, the first quadrature-phase driver PA impedance matching circuit **150** receives and forwards the first quadrature-phase RF input signal FQN to the first quadrature-phase driver PA stage **152**, which receives and amplifies the forwarded first quadrature-phase RF input signal to provide an amplified first quadrature-phase RF input signal to the first quadrature-phase final PA stage **156** via the first quadrature-phase final PA impedance matching circuit **154**. The first quadrature-phase final PA stage **156** receives and amplifies the amplified first quadrature-phase RF input signal to provide the first quadrature-phase RF output signal FQT via the first quadrature-phase combiner impedance matching circuit **158**. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first quadrature-phase driver PA stage **152** and the first quadrature-phase final PA stage **156**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first quadrature-phase driver PA stage **152** and the first quadrature-phase final PA stage **156**.

The second in-phase amplification path **134** includes a second in-phase driver PA impedance matching circuit **160**, a second in-phase driver PA stage **162**, a second in-phase final PA impedance matching circuit **164**, a second in-phase final PA stage **166**, and a second in-phase combiner impedance matching circuit **168**. The second in-phase driver PA impedance matching circuit **160** is coupled between the second in-phase output SIO and the second in-phase driver PA stage **162**. The second in-phase final PA impedance matching circuit **164** is coupled between the second in-phase driver PA stage **162** and the second in-phase final PA stage **166**. The second in-phase combiner impedance matching circuit **168** is coupled between the second in-phase final PA stage **166** and the second in-phase input SII.

The second in-phase driver PA impedance matching circuit **160** may provide at least an approximate impedance match between the second quadrature RF splitter **132** and the second in-phase driver PA stage **162**. The second in-phase final PA impedance matching circuit **164** may provide at least an approximate impedance match between the second in-phase driver PA stage **162** and the second in-phase final PA stage **166**. The second in-phase combiner impedance matching circuit **168** may provide at least an approximate impedance match between the second in-phase final PA stage **166** and the second quadrature RF combiner **138**.

During the second PA operating mode, the second in-phase driver PA impedance matching circuit **160** receives and forwards the second in-phase RF input signal SIN to the second in-phase driver PA stage **162**, which receives and amplifies the forwarded second in-phase RF input signal to provide an amplified second in-phase RF input signal to the second in-phase final PA stage **166** via the second in-phase final PA impedance matching circuit **164**. The second in-phase final PA stage **166** receives and amplifies the amplified second in-phase RF input signal to provide the second in-phase RF output signal SIT via the second in-phase combiner impedance matching circuit **168**. During the second PA operating mode, the envelope power supply signal EPS provides power for amplification to the second in-phase driver PA stage **162** and the second in-phase final PA stage **166**. During the second PA operating mode, the second final bias signal SFB provides biasing to the second in-phase driver PA stage **162** and the second in-phase final PA stage **166**.

The second quadrature-phase amplification path **136** includes a second quadrature-phase driver PA impedance matching circuit **170**, a second quadrature-phase driver PA stage **172**, a second quadrature-phase final PA impedance matching circuit **174**, a second quadrature-phase final PA stage **176**, and a second quadrature-phase combiner impedance matching circuit **178**. The second quadrature-phase driver PA impedance matching circuit **170** is coupled between the second quadrature-phase output SQO and the second quadrature-phase driver PA stage **172**. The second quadrature-phase final PA impedance matching circuit **174** is coupled between the second quadrature-phase driver PA stage **172** and the second quadrature-phase final PA stage **176**. The second quadrature-phase combiner impedance matching circuit **178** is coupled between the second quadrature-phase final PA stage **176** and the second quadrature-phase input SQI.

The second quadrature-phase driver PA impedance matching circuit **170** may provide at least an approximate impedance match between the second quadrature RF splitter **132** and the second quadrature-phase driver PA stage **172**. The second quadrature-phase final PA impedance matching circuit **174** may provide at least an approximate impedance match between the second quadrature-phase driver PA stage **172** and the second quadrature-phase final PA stage **176**. The second quadrature-phase combiner impedance matching circuit **178** may provide at least an approximate impedance match between the second quadrature-phase final PA stage **176** and the second quadrature RF combiner **138**.

During the second PA operating mode, the second quadrature-phase driver PA impedance matching circuit **170** receives and forwards the second quadrature-phase RF input signal SQN to the second quadrature-phase driver PA stage **172**, which receives and amplifies the forwarded second quadrature-phase RF input signal to provide an amplified second quadrature-phase RF input signal to the second quadrature-phase final PA stage **176** via the second quadrature-phase final PA impedance matching circuit **174**. The second quadrature-phase final PA stage **176** receives and amplifies the amplified second quadrature-phase RF input signal to provide the second quadrature-phase RF output signal SQT via the second quadrature-phase combiner impedance matching circuit **178**. During the second PA operating mode, the envelope power supply signal EPS provides power for amplification to the second quadrature-phase driver PA stage **172** and the second quadrature-phase final PA stage **176**. During the second PA operating mode, the second final bias signal SFB provides biasing to the second quadrature-phase driver PA stage **172** and the second quadrature-phase final PA stage **176**.

In alternate embodiments of the first in-phase amplification path **126**, any or all of the first in-phase driver PA impedance matching circuit **140**, the first in-phase driver PA stage **142**, the first in-phase final PA impedance matching circuit **144**, and the first in-phase combiner impedance matching circuit **148** may be omitted. In alternate embodiments of the first quadrature-phase amplification path **128**, any or all of the first quadrature-phase driver PA impedance matching circuit **150**, the first quadrature-phase driver PA stage **152**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase combiner impedance matching circuit **158** may be omitted. In alternate embodiments of the second in-phase amplification path **134**, any or all of the second in-phase driver PA impedance matching circuit **160**, the second in-phase driver PA stage **162**, the second in-phase final PA impedance matching circuit **164**, and the second in-phase combiner impedance matching circuit **168** may be omitted. In alternate embodiments of the second quadrature-phase amplification path **136**, any or all of the second quadrature-phase driver PA impedance matching circuit **170**, the second quadrature-phase driver PA stage **172**, the second quadrature-phase final PA impedance matching circuit **174**, and the second quadrature-phase combiner impedance matching circuit **178** may be omitted.

FIG. **19** shows details of the first quadrature PA path **102** and the second quadrature PA path **106** illustrated in FIG. **15** according to an alternate embodiment of the first quadrature PA path **102** and the second quadrature PA path **106**. The first quadrature PA path **102** and the second quadrature PA path **106** illustrated in FIG. **19** are similar to the first quadrature PA path **102** and the second quadrature PA path **106** illustrated in FIG. **17**, except in the first quadrature PA path **102** and the second quadrature PA path **106** illustrated in FIG. **19**, during the first PA operating mode, the first driver bias signal FDB provides further biasing to the first in-phase amplification path **126** and the first quadrature-phase amplification path **128**, and during the second PA operating mode, the second driver bias signal SDB provides further biasing to the second in-phase amplification path **134** and the second quadrature-phase amplification path **136**.

FIG. **20** shows details of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, the second in-phase amplification path **134**, and the second quadrature-phase amplification path **136** illustrated in FIG. **19** according to an alternate embodiment of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, the second in-phase amplification path **134**, and the second quadrature-phase amplification path **136**. The amplification paths **126**, **128**, **134**, **136** illustrated in FIG. **20** are similar to the amplification paths **126**, **128**, **134**, **136** illustrated in FIG. **18**, except in the amplification paths **126**, **128**, **134**, **136** illustrated in FIG. **20**, during the first PA operating mode, the first driver bias signal FDB provides biasing to the first in-phase driver PA stage **142** and the first quadrature-phase driver PA stage **152** instead of the first final bias signal FFB, and during the second PA operating mode, the second driver bias signal SDB provides biasing to the second in-phase driver PA stage **162** and the second quadrature-phase driver PA stage **172** instead of the second final bias signal SFB.

FIG. **21** shows details of the first RF PA **50** and the second RF PA **54** illustrated in FIG. **14** according an alternate embodiment of the first RF PA **50** and the second RF PA **54**. The first RF PA **50** shown in FIG. **21** is similar to the first RF PA **50** illustrated in FIG. **15**. The second RF PA **54** shown in FIG. **21** is similar to the second RF PA **54** illustrated in FIG. **15**, except in the second RF PA **54** illustrated in FIG. **21** the second quadrature PA path **106** is omitted. As such, during the second PA operating mode, the second RF input signal SRFI provides the second RF feeder output signal SFO to the second quadrature PA path **106**. In this regard, during the second PA operating mode, the second quadrature PA path **106** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO. During the second PA operating mode, the second quadrature PA path **106** receives the envelope power supply signal EPS, which provides power for amplification. Further, during the second PA operating mode, the second quadrature PA path **106** receives the second driver bias signal SDB and the second final bias signal SFB, both of which provide biasing to the second quadrature PA path **106**.

FIG. **22** shows details of the first non-quadrature PA path **100**, the first quadrature PA path **102**, and the second quadrature PA path **106** illustrated in FIG. **21** according to an additional embodiment of the first non-quadrature PA path **100**, the first quadrature PA path **102**, and the second quadrature PA path **106**. The second quadrature PA path **106** illustrated in FIG. **22** is similar to the second quadrature PA path **106** illustrated in FIG. **20**. The first quadrature PA path **102** illustrated in FIG. **22** is similar to the first quadrature PA path **102** illustrated in FIG. **20**, except in the first quadrature PA path **102** illustrated in FIG. **22**, the first in-phase driver PA impedance matching circuit **140**, the first in-phase driver PA stage **142**, the first quadrature-phase driver PA impedance matching circuit **150**, and the first quadrature-phase driver PA stage **152** are omitted. In this regard, the first in-phase final PA impedance matching circuit **144** is coupled between the first in-phase output FIO and the first in-phase final PA stage **146**. The first in-phase combiner impedance matching circuit **148** is coupled between the first in-phase final PA stage **146** and the first in-phase input FII. The first in-phase final PA impedance matching circuit **144** may provide at least an approximate impedance match between the first quadrature RF splitter **124** and the first in-phase final PA stage **146**. The first in-phase combiner impedance matching circuit **148** may provide at least an approximate impedance match between the first in-phase final PA stage **146** and the first quadrature RF combiner **130**.

During the first PA operating mode, the first in-phase final PA impedance matching circuit **144** receives and forwards the first in-phase RF input signal FIN to the first in-phase final PA stage **146**, which receives and amplifies the forwarded first in-phase RF input signal to provide the first in-phase RF output signal FIT via the first in-phase combiner impedance matching circuit **148**. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first in-phase final PA stage **146**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first in-phase final PA stage **146**.

The first quadrature-phase final PA impedance matching circuit **154** is coupled between the first quadrature-phase output FQO and the first quadrature-phase final PA stage **156**. The first quadrature-phase combiner impedance matching circuit **158** is coupled between the first quadrature-phase final PA stage **156** and the first quadrature-phase input FQI. The first quadrature-phase final PA impedance matching circuit **154** may provide at least an approximate impedance match between the first quadrature RF splitter **124** and the first quadrature-phase final PA stage **156**. The first quadrature-phase combiner impedance matching circuit **158** may provide at least an approximate impedance match between the first quadrature-phase final PA stage **156** and the first quadrature RF combiner **130**.

During the first PA operating mode, the first quadrature-phase final PA impedance matching circuit **154** receives and forwards the first quadrature-phase RF input signal FQN to the first quadrature-phase final PA stage **156**, which receives and amplifies the forwarded first quadrature-phase RF input signal to provide the first quadrature-phase RF output signal FQT via the first quadrature-phase combiner impedance matching circuit **158**. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first quadrature-phase final PA stage **156**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first quadrature-phase final PA stage **156**.

The first non-quadrature PA path **100** illustrated in FIG. **22** is similar to the first non-quadrature PA path **100** illustrated in FIG. **16**, except in the first non-quadrature PA path **100** illustrated in FIG. **22**, the first input PA impedance matching circuit **108** and the first input PA stage **110** are omitted. As such, the first feeder PA stage **114** is coupled between the first feeder PA impedance matching circuit **112** and the first quadrature PA path **102**. The first feeder PA impedance matching circuit **112** may provide at least an approximate impedance match between the RF modulation circuitry **44** (FIG. **5**) and the first feeder PA stage **114**. During the first PA operating mode, the first feeder PA impedance matching circuit **112** receives and forwards the first RF input signal FRFI to provide the first RF feeder input signal FFI to the first feeder PA stage **114**. During the first PA operating mode, the first feeder PA stage **114** receives and amplifies the first RF feeder input signal FFI to provide the first RF feeder output signal FFO via the first single-ended output FSO. During the first PA operating mode, the envelope power supply signal EPS provides power for amplification to the first feeder PA stage **114**. During the first PA operating mode, the first final bias signal FFB provides biasing to the first feeder PA stage **114**.

In one embodiment of the first quadrature PA path **102**, the first quadrature PA path **102** has only one in-phase PA stage, which is the first in-phase final PA stage **146**, and only one quadrature-phase PA stage, which is the first quadrature-phase final PA stage **156**. In one embodiment of the second quadrature PA path **106**, the second in-phase driver PA impedance matching circuit **160**, the second in-phase driver PA stage **162**, the second quadrature-phase driver PA impedance matching circuit **170**, and the second quadrature-phase driver PA stage **172** are omitted. As such, the second quadrature PA path **106** has only one in-phase PA stage, which is the second in-phase final PA stage **166**, and only one quadrature-phase PA stage, which is the second quadrature-phase final PA stage **176**.

FIG. **23** shows details of the first feeder PA stage **114** and the first quadrature RF splitter **124** illustrated in FIG. **16** and FIG. **17**, respectively, according to one embodiment of the first feeder PA stage **114** and the first quadrature RF splitter **124**. FIGS. **23** and **24** show only a portion of the first feeder PA stage **114** and the first quadrature RF splitter **124**. The first feeder PA stage **114** includes a first output transistor element **180**, an inverting output inductive element LIO, and the first single-ended output FSO. The first output transistor element **180** has a first transistor inverting output FTIO, a first transistor non-inverting output FTNO, and a first transistor input FTIN. The first transistor non-inverting output FTNO is coupled to a ground and the first transistor inverting output FTIO is coupled to the first single-ended output FSO and to one end of the inverting output inductive element LIO. An opposite end of the inverting output inductive element LIO receives the envelope power supply signal EPS.

The first quadrature RF splitter **124** has the first single-ended input FSI, such that the first input impedance is presented at the first single-ended input FSI. Since the first input impedance may be predominantly resistive, the first input impedance may be approximated as a first input resistive element RFI coupled between the first single-ended input FSI and the ground. The first single-ended output FSO is directly coupled to the first single-ended input FSI. Therefore, the first input resistive element RFI is presented to the first transistor inverting output FTIO.

FIG. **24** shows details of the first feeder PA stage **114** and the first quadrature RF splitter **124** illustrated in FIG. **16** and FIG. **17**, respectively, according to an alternate embodiment of the first feeder PA stage **114** and the first quadrature RF splitter **124**. The first output transistor element **180** is an NPN bipolar transistor element, such that an emitter of the NPN bipolar transistor element provides the first transistor non-inverting output FTNO (FIG. **23**), a base of the NPN bipolar transistor element provides the first transistor input FTIN (FIG. **23**), and a collector of the NPN bipolar transistor element provides the first transistor inverting output FTIO (FIG. **23**). The inverting output inductive element LIO has an inverting output inductor current IDC, the collector of the NPN bipolar transistor element has a collector current IC, and the first input resistive element RFI has a first input current IFR. The NPN bipolar transistor element has a collector-emitter voltage VCE between the emitter and the collector of the NPN bipolar transistor element.

In general, the first feeder PA stage **114** is the feeder PA stage having the single-ended output and an output transistor element, which has an inverting output. In general, the first quadrature RF splitter **124** is the quadrature RF splitter having the single-ended input, such that the input impedance is presented at the single-ended input. The inverting output may provide the single-ended output and may be directly coupled to the single-ended input. The inverting output may be a collector of the output transistor element and the output transistor element has the output load line.

FIG. **25** is a graph illustrating output characteristics of the first output transistor element **180** illustrated in FIG. **24** according to one embodiment of the first output transistor element **180**. The horizontal axis of the graph represents the collector-emitter voltage VCE of the NPN bipolar transistor element and the vertical axis represents the collector current IC of the NPN bipolar transistor element. Characteristic curves **182** of the NPN bipolar transistor element are shown relating the collector-emitter voltage VCE to the collector current IC at different base currents (not shown). The NPN bipolar transistor element has a first output load line **184** having a first load line slope **186**. The first output load line **184** may be represented by an equation for a straight line having the form Y=mX+b, where X represents the horizontal axis, Y represents the vertical axis, b represents the Y-intercept, and m represents the first load line slope **186**. As such, Y=IC, X=VCE, and b=ISAT, which is a saturation current ISAT of the NPN bipolar transistor element. Further, an X-intercept occurs at an off transistor voltage VCO. Substituting into the equation for a straight line provides EQ. 1, as shown below.

$$IC=m(VCE)+ISAT. \qquad \text{EQ. 1}$$

EQ. 2 illustrates Ohm's Law as applied to the first input resistive element RFI, as shown below.

$$VCE=(IFR)(RFI). \qquad \text{EQ. 2:}$$

EQ. 3 illustrates Kirchhoff's Current Law applied to the circuit illustrated in FIG. **24** as shown below.

$$IDC=IC+IFR. \qquad \text{EQ. 3}$$

The inductive reactance of the inverting output inductive element LIO at frequencies of interest may be large compared to the resistance of the first input resistive element RFI. As such, for the purpose of analysis, the inverting output inductor current IDC may be treated as a constant DC current. Therefore, when VCE=0, the voltage across the first input resistive element RFI is zero, which makes IFR=0. From EQ. 3, if IFR=0, then IC=IDC. However, from EQ. 1, when VCE=0 and IC=IDC, then ISAT=IDC, which is a constant. Substituting into EQ. 1 provides EQ. 1A as shown below.

$$IC=m(VCE)+IDC. \qquad \text{EQ. 1A}$$

From FIG. **25**, when IC=0, VCE=VCO. Substituting into EQ. 1A, EQ. 2, and EQ. 3 provides EQ. 1 B, EQ. 2A, and EQ. 3A as shown below.

$$0=m(VCO)+IDC. \qquad \text{EQ. 1B}$$

$$VCO=(IFR)(RFI). \qquad \text{EQ. 2A}$$

$$IDC=0+IFR. \qquad \text{EQ. 3A}$$

EQ. 3A may be substituted into EQ. 2A, which may be substituted into EQ. 1B to provide EQ. 1C as shown below.

$$0=m(VCO)+IDC=m(IDC)(RFI)+IDC. \qquad \text{EQ. 1C}$$

Therefore, m=−1/RFI. As a result, the first load line slope **186**, which is represented by m is determined by the first input resistive element RFI, such that there is a negative inverse relationship between the first load line slope **186** and the first input resistive element RFI. In general, the first load line slope **186** is based on the first input impedance, such that the first input impedance substantially establishes the first load line slope **186**. Further, there may be a negative inverse relationship between the first load line slope **186** and the first input impedance.

FIG. **26** illustrates a process for matching an input impedance, such as the first input impedance to the first quadrature RF splitter **124** (FIG. **16**) to a target load line slope for a feeder PA stage, such as the first feeder PA stage **114** (FIG. **17**). The first step of the process is to determine an operating power range of an RF PA, which has the feeder PA stage feeding a quadrature RF splitter (Step A**10**). The next step of the process is to determine the target load line slope for the feeder PA stage based on the operating power range (Step A**12**). A further step is to determine the input impedance to the quadrature RF splitter that substantially provides the target load line slope (Step A**14**). The final step of the process is to determine an operating frequency range of the RF PA, such that the target load line slope is further based on the operating frequency range (Step A**16**). In an alternate embodiment of the process for matching the input impedance to the target load line slope, the final step (Step A**16**) is omitted.

FIG. **27** shows details of the first RF PA **50** illustrated in FIG. **14** according an alternate embodiment of the first RF PA **50**. The first RF PA **50** illustrated in FIG. **27** is similar to the first RF PA **50** illustrated in FIG. **15**, except the first RF PA **50** illustrated in FIG. **27** further includes a first non-quadrature path power coupler **188**. As previously mentioned, the first quadrature PA path **102** may present a first input impedance at the first single-ended input FSI that is predominantly resistive. Further, the first input impedance may be stable over a wide frequency range and over widely varying antenna loading conditions. As a result, coupling RF power from the first single-ended output FSO may be used for RF power detection or sampling with a high degree of accuracy and directivity. Since the first single-ended input FSI may be directly coupled to the first single-ended output FSO, coupling RF power from the first single-ended output FSO may be equivalent to coupling RF power from the first single-ended input FSI.

The first non-quadrature path power coupler **188** is coupled to the first single-ended output FSO and couples a portion of RF power flowing though the first single-ended output FSO to provide a first non-quadrature path power output signal FNPO. In an additional embodiment of the first RF PA **50**, the first non-quadrature path power coupler **188** is coupled to the first single-ended input FSI and couples a portion of RF power flowing though the first single-ended input FSI to provide the first non-quadrature path power output signal FNPO.

FIG. **28** shows details of the second RF PA **54** illustrated in FIG. **14** according an alternate embodiment of the second RF PA **54**. The second RF PA **54** illustrated in FIG. **28** is similar to the second RF PA **54** illustrated in FIG. **15**, except the second RF PA **54** illustrated in FIG. **28** further includes a second non-quadrature path power coupler **190**. As previously mentioned, the second quadrature PA path **106** may present a second input impedance at the second single-ended input SSI that is predominantly resistive. Further, the second input impedance may be stable over a wide frequency range and over widely varying antenna loading conditions. As a result, coupling RF power from the second single-ended output SSO may be used for RF power detection or sampling with a high degree of accuracy and directivity. Since the second single-ended input SSI may be directly coupled to the second single-ended output SSO, coupling RF power from the second single-ended output SSO may be equivalent to coupling RF power from the second single-ended input SSI.

The second non-quadrature path power coupler **190** is coupled to the second single-ended output SSO and couples a portion of RF power flowing though the second single-ended output SSO to provide a second non-quadrature path power output signal SNPO. In an additional embodiment of the second RF PA **54**, the second non-quadrature path power coupler **190** is coupled to the second single-ended input SSI and couples a portion of RF power flowing though the second single-ended input SSI to provide the second non-quadrature path power output signal SNPO.

FIG. **29** shows details of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, and the first quadrature RF combiner **130** illustrated in FIG. **22** according to one embodiment of the first in-phase amplification path **126**, the first quadrature-phase amplification path **128**, and the first quadrature RF combiner **130**. The first in-phase combiner impedance matching circuit **148** and the first quadrature-phase combiner impedance matching circuit **158** have been omitted from the first in-phase amplification path **126** and the first quadrature-phase amplification path **128**, respectively. The first quadrature RF combiner **130** includes first phase-shifting circuitry **192** and a first Wilkinson RF combiner **194**. The first phase-shifting circuitry **192** has the first in-phase input FII and the first quadrature-phase input FQI. The first Wilkinson RF combiner **194** has the first quadrature combiner output FCO.

During the first PA operating mode, the first phase-shifting circuitry **192** receives and phase-aligns RF signals from the first in-phase final PA stage **146** and the first quadrature-phase final PA stage **156** via the first in-phase input FII and the first quadrature-phase input FQI, respectively, to provide phase-aligned RF signals to the first Wilkinson RF combiner **194**. The first Wilkinson RF combiner **194** combines phase-aligned RF signals to provide the first RF output signal FRFO via the first quadrature combiner output FCO. The first phase-shifting circuitry **192** and the first Wilkinson RF combiner **194** may provide stable input impedances presented at the first in-phase input FII and the first quadrature-phase input FQI, respectively, which allows elimination of the first in-phase combiner impedance matching circuit **148** and the first quadrature-phase combiner impedance matching circuit **158**.

FIG. **30** shows details of the first feeder PA stage **114**, the first quadrature RF splitter **124**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156** illustrated in FIG. **29** according to one embodiment of the first feeder PA stage **114**, the first quadrature RF splitter **124**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156**. Further, FIG. **30** shows a portion of the first phase-shifting circuitry **192** illustrated in FIG. **29**.

The first in-phase final PA stage **146** includes a first in-phase final transistor element **196**, first in-phase biasing circuitry **198**, and a first in-phase collector inductive element LCI. The first quadrature-phase final PA stage **156** includes a first quadrature-phase final transistor element **200**, first quadrature-phase biasing circuitry **202**, and a first quadrature-phase collector inductive element LCQ. The first in-phase final PA impedance matching circuit **144** includes a first in-phase series capacitive element CSI**1**, a second in-phase series capacitive element CSI**2**, and a first in-phase shunt inductive element LUI. The first quadrature-phase final PA impedance matching circuit **154** includes a first quadrature-phase series capacitive element CSQ**1**, a second quadrature-phase series capacitive element CSQ**2**, and a first quadrature-phase shunt inductive element LUQ.

The first quadrature RF splitter **124** includes a first pair **204** of tightly coupled inductors and a first isolation port resistive element RI**1**. The first pair **204** of tightly coupled inductors has first parasitic capacitance **206** between the first pair **204** of tightly coupled inductors. Additionally, the first quadrature RF splitter **124** has the first single-ended input FSI, the first in-phase output FIO, and the first quadrature-phase output FQO. The first feeder PA stage **114** includes the first output transistor element **180**, first feeder biasing circuitry **208**, a first DC blocking capacitive element CD**1**, a first base resistive element RB**1**, and a first collector inductive element LC**1**. Additionally, the first feeder PA stage **114** has the first single-ended output FSO.

The first output transistor element **180** shown is an NPN bipolar transistor element. Other embodiments of the first output transistor element **180** may use other types of transistor elements, such as field effect transistor elements (FET) elements. The first DC blocking capacitive element CD**1** is coupled between the first feeder PA impedance matching circuit **112** (FIG. **22**) and the first base resistive element RB. A base of the first output transistor element **180** and the first feeder biasing circuitry **208** are coupled to the first base resistive element RB**1**. In alternate embodiments of the first feeder PA stage **114**, the first base resistive element RB**1**, the first DC blocking capacitive element CD**1**, or both may be omitted. The first feeder biasing circuitry **208** receives the first driver bias signal FDB. An emitter of the first output transistor element **180** is coupled to a ground. A collector of the first output transistor element **180** is coupled to the first single-ended output FSO. One end of the first collector inductive element LC**1** is coupled to the first single-ended output FSO. An opposite end of the first collector inductive element LC**1** receives the envelope power supply signal EPS. The first single-ended output FSO is coupled to the first single-ended input FSI.

During the first PA operating mode, the first output transistor element **180** receives and amplifies an RF signal from the first feeder PA impedance matching circuit **112** (FIG. **22**) via the first DC blocking capacitive element CD**1** and the first base resistive element RB**1** to provide the first RF feeder output signal FFO (FIG. **29**) to the first single-ended input FSI via the first single-ended output FSO. The envelope power supply signal EPS provides power for amplification via the first collector inductive element LC**1**. The first feeder biasing circuitry **208** biases the first output transistor element **180**. The first driver bias signal FDB provides power for biasing the first output transistor element **180** to the first feeder biasing circuitry **208**.

The first quadrature RF splitter **124** illustrated in FIG. **30** is a quadrature hybrid coupler. In this regard, the first pair **204** of tightly coupled inductors, the first parasitic capacitance **206**, and the first isolation port resistive element RI**1** provide quadrature hybrid coupler functionality. As such, the first single-ended input FSI functions as an input port to the quadrature hybrid coupler, the first in-phase output FIO functions as a zero degree output port from the quadrature hybrid coupler, and the first quadrature-phase output FQO functions as a 90 degree output port from the quadrature hybrid coupler. One of the first pair **204** of tightly coupled inductors is coupled between the first single-ended input FSI and the first in-phase output F**10**. Another of the first pair **204** of tightly coupled inductors has a first end coupled to the first quadrature-phase output FQO and a second end coupled to the first isolation port resistive element RI**1**. As such, the second end functions as an isolation port of the quadrature hybrid coupler. In this regard, the first isolation port resistive element RI**1** is coupled between the isolation port and the ground. The first in-phase output FIO is coupled to the first in-phase series capacitive element CSI**1** and the first quadrature-phase output FQO is coupled to the first quadrature-phase series capacitive element CSQ**1**.

During the first PA operating mode, the first pair **204** of tightly coupled inductors receives, splits, and phase-shifts the first RF feeder output signal FFO (FIG. **29**) from the first single-ended output FSO via the first single-ended input FSI to provide split, phase-shifted output signals to the first in-phase series capacitive element CSI**1** and the first quadrature-phase series capacitive element CSQ**1**. As previously mentioned, the first input impedance is presented at the first single-ended input FSI. As such, the first input impedance is substantially based on the first parasitic capacitance **206** and inductances of the first pair **204** of tightly coupled inductors.

The first in-phase series capacitive element CSI**1** and the second in-phase series capacitive element CSI**2** are coupled in series between the first in-phase output FIO and a base of the first in-phase final transistor element **196**. The first in-phase shunt inductive element LUI is coupled between the ground and a junction between the first in-phase series capacitive element CSI**1** and the second in-phase series capacitive element CSI**2**. The first quadrature-phase series capacitive element CSQ**1** and the second quadrature-phase series capacitive element CSQ**2** are coupled in series between the first quadrature-phase output FQO and a base of the first quadrature-phase final transistor element **200**. The first quadrature-phase shunt inductive element LUQ is coupled between the ground and a junction between the first quadrature-phase series capacitive element CSQ**1** and the second quadrature-phase series capacitive element CSQ**2**.

The first in-phase series capacitive element CSI**1**, the second in-phase series capacitive element CSI**2**, and the first in-phase shunt inductive element LUI form a "T" network, which may provide at least an approximate impedance match between the first in-phase output FIO and the base of the first in-phase final transistor element **196**. Similarly, the first quadrature-phase series capacitive element CSQ**1**, the second quadrature-phase series capacitive element CSQ**2**, and the first quadrature-phase shunt inductive element LUQ form a "T" network, which may provide at least an approximate impedance match between the first quadrature-phase output FQO and the base of the first quadrature-phase final transistor element **200**.

During the first PA operating mode, the first in-phase final PA impedance matching circuit **144** receives and forwards an RF signal from the first in-phase output FIO to the base of the first in-phase final transistor element **196** via the first in-phase series capacitive element CSI**1** and the second in-phase series capacitive element CSI**2**. During the first PA operating mode, the first quadrature-phase final PA impedance matching circuit **154** receives and forwards an RF signal from the first quadrature-phase output FQO to the base of the first quadrature-phase final transistor element **200** via the first quadrature-phase series capacitive element CSQ**1** and the second quadrature-phase series capacitive element CSQ**2**.

The first in-phase final transistor element **196** shown is an NPN bipolar transistor element. Other embodiments of the first in-phase final transistor element **196** may use other types of transistor elements, such as FET elements. The base of the first in-phase final transistor element **196** and the first in-phase biasing circuitry **198** are coupled to the second in-phase series capacitive element CSI**2**. The first in-phase biasing circuitry **198** receives the first final bias signal FFB. An emitter of the first in-phase final transistor element **196** is coupled to the ground. A collector of the first in-phase final transistor element **196** is coupled to the first in-phase input FII. One end of the first in-phase collector inductive element LCI is coupled to the collector of the first in-phase final transistor element **196**. An opposite end of the first in-phase collector inductive element LCI receives the envelope power supply signal EPS.

During the first PA operating mode, the first in-phase final transistor element **196** receives and amplifies an RF signal from the second in-phase series capacitive element CSI**2** to provide an RF output signal to the first in-phase input FII. The envelope power supply signal EPS provides power for amplification via the first in-phase collector inductive element LCI. The first in-phase biasing circuitry **198** biases the first in-phase final transistor element **196**. The first final bias signal FFB provides power for biasing the first in-phase final transistor element **196** to the first in-phase biasing circuitry **198**.

The first quadrature-phase final transistor element **200** shown is an NPN bipolar transistor element. Other embodiments of the first quadrature-phase final transistor element **200** may use other types of transistor elements, such as FET elements. The base of the first quadrature-phase final transistor element **200** and the first quadrature-phase biasing circuitry **202** are coupled to the second quadrature-phase series capacitive element CSQ**2**. The first quadrature-phase biasing circuitry **202** receives the first final bias signal FFB. An emitter of the first quadrature-phase final transistor element **200** is coupled to the ground. A collector of the first quadrature-phase final transistor element **200** is coupled to the first quadrature-phase input FQI. One end of the first quadrature-phase collector inductive element LCQ is coupled to the collector of the first quadrature-phase final transistor element **200**. An opposite end of the first quadrature-phase collector inductive element LCQ receives the envelope power supply signal EPS.

During the first PA operating mode, the first quadrature-phase final transistor element **200** receives and amplifies an RF signal from the second quadrature-phase series capacitive element CSQ**2** to provide an RF output signal to the first quadrature-phase input FQI. The envelope power supply signal EPS provides power for amplification via the first quadrature-phase collector inductive element LCQ. The first quadrature-phase biasing circuitry **202** biases the first quadrature-phase final transistor element **200**. The first final bias signal FFB provides power for biasing the first quadrature-phase final transistor element **200** to the first quadrature-phase biasing circuitry **202**.

In one embodiment of the RF PA circuitry **30** (FIG. **5**), the RF PA circuitry **30** includes a first PA semiconductor die **210**. In one embodiment of the first PA semiconductor die **210**, the first PA semiconductor die **210** includes the first output transistor element **180**, the first in-phase final transistor element **196**, the first in-phase biasing circuitry **198**, the first quadrature-phase final transistor element **200**, the first quadrature-phase biasing circuitry **202**, the first pair **204** of tightly coupled inductors, the first feeder biasing circuitry **208**, the first in-phase series capacitive element CSI**1**, the second in-phase series capacitive element CSI**2**, the first quadrature-phase series capacitive element CSQ**1**, the second quadrature-phase series capacitive element CSQ**2**, the first isolation port resistive element RI**1**, the first base resistive element RB**1**, and the first DC blocking capacitive element CD**1**.

In alternate embodiments of the first PA semiconductor die **210**, the first PA semiconductor die **210** may not include any or all of the first output transistor element **180**, the first in-phase final transistor element **196**, the first in-phase biasing circuitry **198**, the first quadrature-phase final transistor element **200**, the first quadrature-phase biasing circuitry **202**, the first pair **204** of tightly coupled inductors, the first feeder biasing circuitry **208**, the first in-phase series capacitive element CSI**1**, the second in-phase series capacitive element CSI**2**, the first quadrature-phase series capacitive element CSQ**1**, the second quadrature-phase series capacitive element CSQ**2**, the first isolation port resistive element RI**1**, the first base resistive element RB**1**, and the first DC blocking capacitive element CD**1**.

FIG. **31** shows details of the first feeder PA stage **114**, the first quadrature RF splitter **124**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156** illustrated in FIG. **29** according to an alternate embodiment of the first feeder PA stage **114**, the first quadrature RF splitter **124**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156**. Further, FIG. **31** shows a portion of the first phase-shifting circuitry **192** illustrated in FIG. **29**.

The first feeder PA stage **114**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156** illustrated in FIG. **31** are similar to the first feeder PA stage **114**, the first in-phase final PA impedance matching circuit **144**, the first in-phase final PA stage **146**, the first quadrature-phase final PA impedance matching circuit **154**, and the first quadrature-phase final PA stage **156** illustrated in FIG. **30**. The first quadrature RF splitter **124** illustrated in FIG. **31** is similar to the first quadrature RF splitter **124** illustrated in FIG. **30**, except the first quadrature RF splitter **124** illustrated in FIG. **31** further includes a first coupler capacitive element CC**1** coupled between the first pair **204** of tightly coupled inductors and a second coupler capacitive element CC**2** coupled between the first pair **204** of tightly coupled inductors. Specifically, the first coupler capacitive element CC**1** is coupled between the first in-phase output FIO and the first isolation port resistive element RI**1**. The second coupler capacitive element CC**2** is coupled between the first single-ended input FSI and the first quadrature-phase output FQO.

The first input impedance is substantially based on the first parasitic capacitance **206**, inductances of the first pair **204** of tightly coupled inductors, the first coupler capacitive element CC**1**, and the second coupler capacitive element CC**2**. In general, the first input impedance is based on the first parasitic capacitance **206** and inductances of the first pair **204** of tightly coupled inductors. The first input impedance is further based on at least one coupler capacitive element, such as the first coupler capacitive element CC**1**, the second coupler capacitive element CC**2**, or both, coupled between the first pair **204** of tightly coupled inductors. In an alternate embodiment of the first quadrature RF splitter **124**, either the first coupler capacitive element CCI or the second coupler capacitive element CC**2** is omitted.

FIG. **32** shows details of the first phase-shifting circuitry **192** and the first Wilkinson RF combiner **194** illustrated in FIG. **29** according to one embodiment of the first phase-shifting circuitry **192** and the first Wilkinson RF combiner **194**. The first phase-shifting circuitry **192** includes a first in-phase phase-shift capacitive element CPI**1**, a first quadrature-phase phase-shift capacitive element CPQ**1**, a first in-phase phase-shift inductive element LPI**1**, and a first quadrature-phase phase-shift inductive element LPQ**1**. The first Wilkinson RF combiner **194** includes a first Wilkinson resistive element RW**1**, a first Wilkinson capacitive element CW**1**, a first Wilkinson in-phase side capacitive element CWI**1**, a first Wilkinson quadrature-phase side capacitive element CWQ**1**, a first Wilkinson in-phase side inductive element LWI**1**, a first Wilkinson quadrature-phase side inductive element LWQ**1**, a second DC blocking capacitive element CD**2**, a third DC blocking capacitive element CD**3**, and a fourth DC blocking capacitive element CD**4**

The first in-phase phase-shift capacitive element CPI**1** is coupled between the first in-phase input FII and a first internal node (not shown). The first in-phase phase-shift inductive element LPI**1** is coupled between the first internal node and the ground. The first quadrature-phase phase-shift inductive element LPQ**1** is coupled between the first quadrature-phase input FQI and a second internal node (not shown). The first quadrature-phase phase-shift capacitive element CPQ**1** is coupled between the second internal node and the ground. The second DC blocking capacitive element CD**2** and the first Wilkinson resistive element RW**1** are coupled in series between the first internal node and the second internal node. The first Wilkinson in-phase side capacitive element CWI**1** is coupled between the first internal node and the ground. The first Wilkinson quadrature-phase side capacitive element CWQ**1** is coupled between the first internal node and the ground. The first Wilkinson in-phase side inductive element LWI**1** is coupled in series with the third DC blocking capacitive element CD**3** between the first internal node and the first quadrature combiner output FCO. The first Wilkinson quadrature-phase side inductive element LWQ**1** is coupled in series with the fourth DC blocking capacitive element CD**4** between the second internal node and the first quadrature combiner output FCO. The first Wilkinson capacitive element CW**1** is coupled between the first quadrature combiner output FCO and the ground.

FIG. **33** shows details of the second non-quadrature PA path **104** illustrated in FIG. **16** and details of the second quadrature PA path **106** illustrated in FIG. **18** according to one embodiment of the second non-quadrature PA path **104** and the second quadrature PA path **106**. Further, FIG. **33** shows details of the second quadrature RF combiner **138** illustrated in FIG. **18** according to one embodiment of the second quadrature RF combiner **138** illustrated in FIG. **18**. The second input PA impedance matching circuit **116**, the second input PA stage **118**, the second in-phase driver PA impedance matching circuit **160**, the second in-phase driver PA stage **162**, the second in-phase combiner impedance matching circuit **168**, the second quadrature-phase driver PA impedance matching circuit **170**, the second quadrature-phase driver PA stage **172**, and the second quadrature-phase combiner impedance matching circuit **178** have been omitted from the second non-quadrature PA path **104** and the second quadrature PA path **106**.

The second quadrature RF combiner **138** includes second phase-shifting circuitry **212** and a second Wilkinson RF combiner **214**. The second phase-shifting circuitry **212** has the second in-phase input SII and the second quadrature-phase input SQI, and the second Wilkinson RF combiner **214** has the second quadrature combiner output SCO.

During the second PA operating mode, the second phase-shifting circuitry **212** receives and phase-aligns RF signals from the second in-phase final PA stage **166** and the second quadrature-phase final PA stage **176** via the second in-phase input SII and the second quadrature-phase input SQI, respectively, to provide phase-aligned RF signals to the second Wilkinson RF combiner **214**. The second Wilkinson RF combiner **214** combines phase-aligned RF signals to provide the second RF output signal SRFO via the second quadrature combiner output SCO. The second phase-shifting circuitry **212** and the second Wilkinson RF combiner **214** may provide stable input impedances presented at the second in-phase input SII and the second quadrature-phase input SQI, respectively, which allows elimination of the second in-phase combiner impedance matching circuit **168** and the second quadrature-phase combiner impedance matching circuit **178**.

FIG. **34** shows details of the second feeder PA stage **122**, the second quadrature RF splitter **132**, the second in-phase final PA impedance matching circuit **164**, the second in-phase final PA stage **166**, the second quadrature-phase final PA impedance matching circuit **174**, and the second quadrature-phase final PA stage **176** illustrated in FIG. **33** according to one embodiment of the second feeder PA stage **122**, the second quadrature RF splitter **132**, the second in-phase final PA impedance matching circuit **164**, the second in-phase final PA stage **166**, the second quadrature-phase final PA impedance matching circuit **174**, and the second quadrature-phase final PA stage **176**. Further, FIG. **34** shows a portion of the second phase-shifting circuitry **212** illustrated in FIG. **33**.

The second in-phase final PA stage **166** includes a second in-phase final transistor element **216**, second in-phase biasing circuitry **218**, and a second in-phase collector inductive element LLI. The second quadrature-phase final PA stage **176** includes a second quadrature-phase final transistor element **220**, a second quadrature-phase biasing circuitry **222**, and a second quadrature-phase collector inductive element LLQ. The second in-phase final PA impedance matching circuit **164** includes a third in-phase series capacitive element CSI**3**, a fourth in-phase series capacitive element CSI**4**, and a second in-phase shunt inductive element LNI. The second quadrature-phase final PA impedance matching circuit **174** includes a third quadrature-phase series capacitive element CSQ**3**, a fourth quadrature-phase series capacitive element CSQ**4**, and a second quadrature-phase shunt inductive element LNQ.

The second quadrature RF splitter **132** includes a second pair **224** of tightly coupled inductors and a second isolation port resistive element RI**2**. The second pair **224** of tightly coupled inductors has second parasitic capacitance **226** between the second pair **224** of tightly coupled inductors. Additionally, the second quadrature RF splitter **132** has the second single-ended input SSI, the second in-phase output SIO, and the second quadrature-phase output SQO. The second feeder PA stage **122** includes a second output transistor element **228**, second feeder biasing circuitry **230**, a fifth DC blocking capacitive element CD**5**, a second base resistive element RB**2**, and a second collector inductive element LC**2**. Additionally, the second feeder PA stage **122** has the second single-ended output SSO.

The second output transistor element **228** shown is an NPN bipolar transistor element. Other embodiments of the second output transistor element **228** may use other types of transistor elements, such as field effect transistor elements (FET) elements. The fifth DC blocking capacitive element CD**5** is coupled between the second feeder PA impedance matching circuit **120** (FIG. **33**) and the second base resistive element RB**2**. A base of the second output transistor element **228** and the second feeder biasing circuitry **230** are coupled to the second base resistive element RB**2**. In alternate embodiments of the second feeder PA stage **122**, the second base resistive element RB**2**, the fifth DC blocking capacitive element CD**5**, or both may be omitted. The second feeder biasing circuitry **230** receives the second driver bias signal SDB. An emitter of the second output transistor element **228** is coupled to a ground. A collector of the second output transistor element **228** is coupled to the second single-ended output SSO. One end of the second collector inductive element LC**2** is coupled to the second single-ended output SSO. An opposite end of the second collector inductive element LC**2** receives the envelope power supply signal EPS. The second single-ended output SSO is coupled to the second single-ended input SSI.

During the second PA operating mode, the second output transistor element **228** receives and amplifies an RF signal from the second feeder PA impedance matching circuit **120** (FIG. **33**) via the fifth DC blocking capacitive element CD**5** and the second base resistive element RB**2** to provide the second RF feeder output signal SFO (FIG. **33**) to the second single-ended input SSI via the second single-ended output SSO. The envelope power supply signal EPS provides power for amplification via the second collector inductive element LC**2**. The second feeder biasing circuitry **230** biases the second output transistor element **228**. The second driver bias signal SDB provides power for biasing the second output transistor element **228** to the second feeder biasing circuitry **230**.

The second quadrature RF splitter **132** illustrated in FIG. **34** is a quadrature hybrid coupler. In this regard, the second pair **224** of tightly coupled inductors, the second parasitic capacitance **226**, and the second isolation port resistive element RI**2** provide quadrature hybrid coupler functionality. As such, the second single-ended input SSI functions as an input port to the quadrature hybrid coupler, the second in-phase output SIO functions as a zero degree output port from the quadrature hybrid coupler, and the second quadrature-phase output SQO functions as a 90 degree output port from the quadrature hybrid coupler. One of the second pair **224** of tightly coupled inductors is coupled between the second single-ended input SSI and the second in-phase output SIO. Another of the second pair **224** of tightly coupled inductors has a first end coupled to the second quadrature-phase output SQO and a second end coupled to the second isolation port resistive element RI**2**. As such, the second end functions as an isolation port of the quadrature hybrid coupler. In this regard, the second isolation port resistive element RI**2** is coupled between the isolation port and the ground. The second in-phase output SIO is coupled to the third in-phase series capacitive element CSI**3** and the second quadrature-phase output SQO is coupled to the third quadrature-phase series capacitive element CSQ**3**.

During the second PA operating mode, the second pair **224** of tightly coupled inductors receives, splits, and phase-shifts the second RF feeder output signal SFO (FIG. **33**) from the second single-ended output SSO via the second single-ended input SSI to provide split, phase-shifted output signals to the third in-phase series capacitive element CSI**3** and the third quadrature-phase series capacitive element CSQ**3**. As previously mentioned, the second input impedance is presented at the second single-ended input SSI. As such, the second input impedance is substantially based on the second parasitic capacitance **226** and inductances of the second pair **224** of tightly coupled inductors.

The third in-phase series capacitive element CSI**3** and the fourth in-phase series capacitive element CSI**4** are coupled in series between the second in-phase output SIO and a base of the second in-phase final transistor element **216**. The second in-phase shunt inductive element LNI is coupled between the ground and a junction between the third in-phase series capacitive element CSI**3** and the fourth in-phase series capacitive element CSI**4**. The third quadrature-phase series capacitive element CSQ**3** and the fourth quadrature-phase series capacitive element CSQ**4** are coupled in series between the second quadrature-phase output SQO and a base of the second quadrature-phase final transistor element **220**. The second quadrature-phase shunt inductive element LNQ is coupled between the ground and a junction between the third quadrature-phase series capacitive element CSQ**3** and the fourth quadrature-phase series capacitive element CSQ**4**.

The third in-phase series capacitive element CSI**3**, the fourth in-phase series capacitive element CSI**4**, and the second in-phase shunt inductive element LNI form a “T” network, which may provide at least an approximate impedance match between the second in-phase output SIO and the base of the second in-phase final transistor element **216**. Similarly, the third quadrature-phase series capacitive element CSQ**3**, the fourth quadrature-phase series capacitive element CSQ**4**, and the second quadrature-phase shunt inductive element LNQ form a “T” network, which may provide at least an approximate impedance match between the second quadrature-phase output SQO and the base of the second quadrature-phase final transistor element **220**.

During the second PA operating mode, the second in-phase final PA impedance matching circuit **164** receives and forwards an RF signal from the second in-phase output SIO to the base of the second in-phase final transistor element **216** via the third in-phase series capacitive element CSI**3** and the fourth in-phase series capacitive element CSI**4**. During the second PA operating mode, the second quadrature-phase final PA impedance matching circuit **174** receives and forwards an RF signal from the second quadrature-phase output SQO to the base of the second quadrature-phase final transistor element **220** via the third quadrature-phase series capacitive element CSQ**3** and the fourth quadrature-phase series capacitive element CSQ**4**. The second in-phase final transistor element **216** shown is an NPN bipolar transistor element. Other embodiments of the second in-phase final transistor element **216** may use other types of transistor elements, such as FET elements. The base of the second in-phase final transistor element **216** and the second in-phase biasing circuitry **218** are coupled to the fourth in-phase series capacitive element CSI**4**.

The second in-phase biasing circuitry **218** receives the second final bias signal SFB. An emitter of the second in-phase final transistor element **216** is coupled to the ground. A collector of the second in-phase final transistor element **216** is coupled to the second in-phase input SII. One end of the second in-phase collector inductive element LLI is coupled to the collector of the second in-phase final transistor element

216. An opposite end of the second in-phase collector inductive element LLI receives the envelope power supply signal EPS.

During the second PA operating mode, the second in-phase final transistor element **216** receives and amplifies an RF signal from the fourth in-phase series capacitive element CSI**4** to provide an RF output signal to the second in-phase input SII. The envelope power supply signal EPS provides power for amplification via the second in-phase collector inductive element LLI. The second in-phase biasing circuitry **218** biases the second in-phase final transistor element **216**. The second final bias signal SFB provides power for biasing the second in-phase final transistor element **216** to the second in-phase biasing circuitry **218**.

The second quadrature-phase final transistor element **220** shown is an NPN bipolar transistor element. Other embodiments of the second quadrature-phase final transistor element **220** may use other types of transistor elements, such as FET elements. The base of the second quadrature-phase final transistor element **220** and the second quadrature-phase biasing circuitry **222** are coupled to the fourth quadrature-phase series capacitive element CSQ**4**. The second quadrature-phase biasing circuitry **222** receives the second final bias signal SFB. An emitter of the second quadrature-phase final transistor element **220** is coupled to the ground. A collector of the second quadrature-phase final transistor element **220** is coupled to the second quadrature-phase input SQI. One end of the second quadrature-phase collector inductive element LLQ is coupled to the collector of the second quadrature-phase final transistor element **220**. An opposite end of the second quadrature-phase collector inductive element LLQ receives the envelope power supply signal EPS.

During the second PA operating mode, the second quadrature-phase final transistor element **220** receives and amplifies an RF signal from the fourth quadrature-phase series capacitive element CSQ**4** to provide an RF output signal to the second quadrature-phase input SQI. The envelope power supply signal EPS provides power for amplification via the second quadrature-phase collector inductive element LLQ. The second quadrature-phase biasing circuitry **222** biases the second quadrature-phase final transistor element **220**. The second final bias signal SFB provides power for biasing the second quadrature-phase final transistor element **220** to the second quadrature-phase biasing circuitry **222**.

In one embodiment of the RF PA circuitry **30** (FIG. **5**), the RF PA circuitry **30** includes a second PA semiconductor die **232**. In one embodiment of the second PA semiconductor die **232**, the second PA semiconductor die **232** includes the second output transistor element **228**, second in-phase final transistor element **216**, second in-phase biasing circuitry **218**, the second quadrature-phase final transistor element **220**, second quadrature-phase biasing circuitry **222**, the second pair **224** of tightly coupled inductors, the second feeder biasing circuitry **230**, the third in-phase series capacitive element CSI**3**, the fourth in-phase series capacitive element CSI**4**, the third quadrature-phase series capacitive element CSQ**3**, the fourth quadrature-phase series capacitive element CSQ**4**, the second isolation port resistive element RI**2**, the second base resistive element RB**2**, and the fifth DC blocking capacitive element CD**5**.

In alternate embodiments of the second PA semiconductor die **232**, the second PA semiconductor die **232** may not include any or all of the second output transistor element **228**, the second in-phase final transistor element **216**, the second in-phase biasing circuitry **218**, the second quadrature-phase final transistor element **220**, the second quadrature-phase biasing circuitry **222**, the second pair **224** of tightly coupled inductors, the second feeder biasing circuitry **230**, the third in-phase series capacitive element CSI**3**, the fourth in-phase series capacitive element CSI**4**, the third quadrature-phase series capacitive element CSQ**3**, the fourth quadrature-phase series capacitive element CSQ**4**, the second isolation port resistive element RI**2**, the second base resistive element RB**2**, and the fifth DC blocking capacitive element CD**5**.

FIG. **35** shows details of the second phase-shifting circuitry **212** and the second Wilkinson RF combiner **214** illustrated in FIG. **33** according to one embodiment of the second phase-shifting circuitry **212** and the second Wilkinson RF combiner **214**. The second phase-shifting circuitry **212** includes a second in-phase phase-shift capacitive element CPI**2**, a second quadrature-phase phase-shift capacitive element CPQ**2**, a second in-phase phase-shift inductive element LPI**2**, and a second quadrature-phase phase-shift inductive element LPQ**2**. The second Wilkinson RF combiner **214** includes a second Wilkinson resistive element RW**2**, a second Wilkinson capacitive element CW**2**, a second Wilkinson in-phase side capacitive element CWI**2**, a second Wilkinson quadrature-phase side capacitive element CWQ**2**, a second Wilkinson in-phase side inductive element LWI**2**, a second Wilkinson quadrature-phase side inductive element LWQ**2**, a sixth DC blocking capacitive element CD**6**, a seventh DC blocking capacitive element CD**7**, and a eighth DC blocking capacitive element CD**8**.

The second in-phase phase-shift capacitive element CPI**2** is coupled between the second in-phase input SII and a third internal node (not shown). The second in-phase phase-shift inductive element LPI**2** is coupled between the third internal node and the ground. The second quadrature-phase phase-shift inductive element LPQ**2** is coupled between the second quadrature-phase input SQI and a fourth internal node (not shown). The second quadrature-phase phase-shift capacitive element CPQ**2** is coupled between the fourth internal node and the ground. The sixth DC blocking capacitive element CD**6** and the second Wilkinson resistive element RW**2** are coupled in series between the third internal node and the fourth internal node. The second Wilkinson in-phase side capacitive element CWI**2** is coupled between the third internal node and the ground. The second Wilkinson quadrature-phase side capacitive element CWQ**2** is coupled between the third internal node and the ground. The second Wilkinson in-phase side inductive element LWI**2** is coupled in series with the seventh DC blocking capacitive element CD**7** between the third internal node and the second quadrature combiner output SCO. The second Wilkinson quadrature-phase side inductive element LWQ**2** is coupled in series with the eighth DC blocking capacitive element CD**8** between the fourth internal node and the second quadrature combiner output SCO. The second Wilkinson capacitive element CW**2** is coupled between the second quadrature combiner output SCO and the ground.

FIG. **36** shows details of the first PA semiconductor die **210** illustrated in FIG. **30** according to one embodiment of the first PA semiconductor die **210**. The first PA semiconductor die **210** includes a first substrate and functional layers **234**, multiple insulating layers **236**, and multiple metallization layers **238**. Some of the insulating layers **236** may be used to separate some of the metallization layers **238** from one another. In one embodiment of the metallization layers **238**, each of the metallization layers **238** is about parallel to at least another of the metallization layers **238**. In this regard the metallization layers **238** may be planar. In an alternate embodiment of the metallization layers **238**, the metallization layers **238** are formed over a non-planar structure, such that spacing between pairs of the metallization layers **238** is about constant. In one embodiment of the metallization layers **238**, each of the first pair **204** of tightly coupled inductors (FIG. **30**) is constructed using at least one of the metallization layers **238**.

Linear Mode and Non-Linear Mode Quadrature PA Circuitry

A summary of linear mode and non-linear mode quadrature PA circuitry is presented, followed by a detailed description of the linear mode and non-linear mode quadrature PA circuitry according to one embodiment of the present disclosure. Multi-mode multi-band RF PA circuitry includes a multi-mode multi-band quadrature RF PA coupled to multi-mode multi-band switching circuitry via a single output. The switching circuitry provides at least one non-linear mode output and multiple linear mode outputs. The non-linear mode output may be associated with at least one non-linear mode RF communications band and each linear mode output may be associated with a corresponding linear mode RF communications band. The outputs from the switching circuitry may be coupled to an antenna port via front-end aggregation circuitry. The quadrature nature of the quadrature PA path may provide tolerance for changes in antenna loading conditions.

One embodiment of the RF PA circuitry includes a highband multi-mode multi-band quadrature RF PA coupled to highband multi-mode multi-band switching circuitry and a lowband multi-mode multi-band quadrature RF PA coupled to lowband multi-mode multi-band switching circuitry. The highband switching circuitry may be associated with at least one highband non-linear mode RF communications band and multiple highband linear mode RF communications bands. The lowband switching circuitry may be associated with at least one lowband non-linear mode RF communications band and multiple lowband linear mode RF communications bands.

FIG. **37** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to one embodiment of the RF PA circuitry **30**. The RF PA circuitry **30** illustrated in FIG. **37** is similar to the RF PA circuitry **30** illustrated in FIG. **8**, except in the RF PA circuitry **30** illustrated in FIG. **37**, the first RF PA **50** is a first multi-mode multi-band quadrature RF PA; the second RF PA **54** is a second multi-mode multi-band quadrature RF PA; the alpha switching circuitry **52** is multi-mode multi-band RF switching circuitry; the first RF PA **50** includes a single alpha PA output SAP; the second RF PA **54** includes a single beta PA output SBP; the alpha switching circuitry **52** further includes a first alpha non-linear mode output FANO, a first alpha linear mode output FALO, and up to and including an R^{TH} alpha linear mode output RALO; and the beta switching circuitry **56** further includes a first beta non-linear mode output FBNO, a first beta linear mode output FBLO, and up to and including an S^{TH} beta linear mode output SBLO. In general, the alpha switching circuitry **52** includes a group of alpha linear mode outputs FALO, RALO and the beta switching circuitry **56** includes a group of beta linear mode outputs FBLO, SBLO.

The first RF PA **50** is coupled to the alpha switching circuitry **52** via the single alpha PA output SAP. The second RF PA **54** is coupled to the beta switching circuitry **56** via the single beta PA output SBP. In one embodiment of the first RF PA **50**, the single alpha PA output SAP is a single-ended output. In one embodiment of the second RF PA **54**, the single beta PA output SBP is a single-ended output. In one embodiment of the alpha switching circuitry **52**, the first alpha non-linear mode output FANO is associated with a first non-linear mode RF communications band and each of the group of alpha linear mode outputs FALO, RALO is associated with a corresponding one of a first group of linear mode RF communications bands. In one embodiment of the beta switching circuitry **56**, the first beta non-linear mode output FBNO is associated with a second non-linear mode RF communications band and each of the group of beta linear mode outputs FBLO, SBLO is associated with a corresponding one of a second group of linear mode RF communications bands.

In an alternate embodiment of the alpha switching circuitry **52**, the first alpha non-linear mode output FANO is associated with a first group of non-linear mode RF communications bands, which includes the first non-linear mode RF communications band. In an alternate embodiment of the beta switching circuitry **56**, the first beta non-linear mode output FBNO is associated with a second group of non-linear mode RF communications bands, which includes the second non-linear mode RF communications band.

In one embodiment of the RF communications system **26** (FIG. **5**), the RF communications system **26** operates in one of a group of communications modes. Control circuitry, which may include the control circuitry **42** (FIG. **5**), the PA control circuitry **94** (FIG. **13**), or both, selects one of the group of communications modes. In one embodiment of the RF communications system **26**, the group of communications modes includes a first alpha non-linear mode and a group of alpha linear modes. In an alternate embodiment of the RF communications system **26**, the group of communications modes includes the first alpha non-linear mode, the group of alpha linear modes, a first beta non-linear mode, and a group of beta non-linear modes. In an additional embodiment of the RF communications system **26**, the group of communications modes includes a group of alpha non-linear modes, the group of alpha linear modes, a group of beta non-linear modes, and the group of beta non-linear modes. Other embodiments of the RF communications system **26** may omit any or all of the communications modes. In one embodiment of the first alpha non-linear mode, the first alpha non-linear mode is a half-duplex mode. In one embodiment of the first beta non-linear mode, the beta alpha non-linear mode is a half-duplex mode. In one embodiment of the group of alpha linear modes, each of the group of alpha linear modes is a full-duplex mode. In one embodiment of the group of beta linear modes, each of the group of beta linear modes is a full-duplex mode.

In one embodiment of the first RF PA **50**, during the first alpha non-linear mode and during each of the group of alpha linear modes, the first RF PA **50** receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO via the single alpha PA output SAP. Further, during the first beta non-linear mode and during each of the group of beta linear modes, the first RF PA **50** does not receive or amplify the first RF input signal FRFI to provide the first RF output signal FRFO.

In one embodiment of the second RF PA **54**, during the first beta non-linear mode and during each of the group of beta linear modes, the second RF PA **54** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO via the single beta PA output SBP. Further, during the first alpha non-linear mode and during each of the group of alpha linear modes, the second RF PA **54** does not receive or amplify the second RF input signal SRFI to provide the second RF output signal SRFO.

In one embodiment of the alpha switching circuitry **52**, during the first alpha non-linear mode, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide the first alpha RF transmit signal FATX via the first alpha non-linear mode output FANO. During a first alpha linear mode, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide the second alpha RF transmit signal SATX via the first alpha linear mode output FALO. During an R^{TH} alpha linear mode, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide the P^{TH} alpha RF transmit signal PATX. In general, during each of the group of alpha linear modes, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide a corresponding one of a group of alpha RF transmit signals SATX, PATX via a corresponding one of the group of alpha linear mode outputs FALO, RALO.

In one embodiment of the beta switching circuitry **56**, during the first beta non-linear mode, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide the first beta RF transmit signal FBTX via the first beta non-linear mode output FBNO. During a first beta linear mode, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide the second beta RF transmit signal SBTX via the first beta linear mode output FBLO. During an S^{TH} beta linear mode, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide the Q^{TH} beta RF transmit signal QBTX. In general, during each of the group of beta linear modes, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide a corresponding one of a group of beta RF transmit signals SBTX, QBTX via a corresponding one of the group of beta linear mode outputs FBLO, SBLO.

FIG. **38** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to an alternate embodiment of the RF PA circuitry **30**. The RF PA circuitry **30** illustrated in FIG. **38** is similar to the RF PA circuitry **30** illustrated in FIG. **9**, except in the RF PA circuitry **30** illustrated in FIG. **38**, the first RF PA **50** is the first multi-mode multi-band quadrature RF PA; the second RF PA **54** is the second multi-mode multi-band quadrature RF PA; the alpha switching circuitry **52** is multi-mode multi-band RF switching circuitry; the first RF PA **50** includes the single alpha PA output SAP; the second RF PA **54** includes the single beta PA output SBP; the alpha switching circuitry **52** further includes the first alpha non-linear mode output FANO, a second alpha non-linear mode output SANO, the first alpha linear mode output FALO, and up to and including the R^{TH} alpha linear mode output RALO; and the beta switching circuitry **56** further includes the first beta non-linear mode output FBNO, a second beta non-linear mode output SBNO, the first beta linear mode output FBLO, and up to and including the S^{TH} beta linear mode output SBLO. In general, the alpha switching circuitry **52** includes the group of alpha linear mode outputs FALO, RALO and the beta switching circuitry **56** includes the group of beta linear mode outputs FBLO, SBLO. Additionally, in general, the alpha switching circuitry **52** includes at least the first alpha harmonic filter **70** and the beta switching circuitry **56** includes at least the first beta harmonic filter **74**.

Dual-Path PA Circuitry with Harmonic Filters

A summary of dual-path PA circuitry with harmonic filters is presented, followed by a detailed description of the dual-path PA circuitry with harmonic filters according to one embodiment of the present disclosure. The dual-path PA circuitry includes a first transmit path and a second transmit path. Each transmit path has an RF PA and switching circuitry having at least one harmonic filter. Each RF PA may be coupled to its corresponding switching circuitry via a single output. Each switching circuitry provides at least one output via a harmonic filter and multiple outputs without harmonic filtering. The output via the harmonic filter may be a non-linear mode output and the outputs without harmonic filtering may be linear mode outputs. The non-linear mode output may be associated with at least one non-linear mode RF communications band and the linear mode outputs may be associated with multiple linear mode RF communications bands. As such, each RF PA may be a multi-mode multi-band RF PA.

The outputs from the switching circuitry may be coupled to an antenna port via front-end aggregation circuitry. The quadrature nature of the quadrature PA path may provide tolerance for changes in antenna loading conditions. One embodiment of the RF PA circuitry includes a highband multi-mode multi-band quadrature RF PA coupled to highband multi-mode multi-band switching circuitry and a lowband multi-mode multi-band quadrature RF PA coupled to lowband multi-mode multi-band switching circuitry. The highband switching circuitry may be associated with at least one highband non-linear mode RF communications band and multiple highband linear mode RF communications bands. The lowband switching circuitry may be associated with at least one lowband non-linear mode RF communications band and multiple lowband linear mode RF communications bands.

In one embodiment of the RF PA circuitry **30**, the first alpha non-linear mode output FANO is a first alpha output, the second alpha non-linear mode output SANO is a second alpha output, the first beta non-linear mode output FBNO is a first beta output, the second beta non-linear mode output SBNO is a second beta output, the group of alpha linear mode outputs FALO, RALO is a group of alpha outputs, and the group of beta linear mode outputs FBLO, SBLO is a group of beta outputs. The alpha switching circuitry **52** provides the first alpha output via the first alpha harmonic filter **70**. The alpha switching circuitry **52** provides the second alpha output via the second alpha harmonic filter **76**. The alpha switching circuitry **52** provides the group of alpha outputs without harmonic filtering. The beta switching circuitry **56** provides the first beta output via the first beta harmonic filter **74**. The beta switching circuitry **56** provides the second beta output via the second beta harmonic filter **78**. The beta switching circuitry **56** provides the group of beta outputs without harmonic filtering.

In one embodiment of the RF communications system **26** (FIG. **5**), the RF communications system **26** operates in one of a group of communications modes. Control circuitry, which may include the control circuitry **42** (FIG. **5**), the PA control circuitry **94** (FIG. **13**), or both, selects one of the group of communications modes. In one embodiment of the RF communications system **26**, the group of communications modes includes the first alpha non-linear mode, the group of alpha linear modes, the first beta non-linear mode, and the group of beta non-linear modes. Other embodiments of the RF communications system **26** may omit any or all of the communications modes. In one embodiment of the first alpha non-linear mode, the first alpha non-linear mode is a half-duplex mode. In one embodiment of the first beta non-linear mode, the beta alpha non-linear mode is a half-duplex mode. In one embodiment of the group of alpha linear modes, each of the group of alpha linear modes is a full-duplex mode. In one embodiment of the group of beta linear modes, each of the group of beta linear modes is a full-duplex mode.

In one embodiment of the first RF PA **50**, during the first alpha non-linear mode and during each of the group of alpha linear modes, the first RF PA **50** receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO via the single alpha PA output SAP. Further, during the first beta non-linear mode and during each of the group of beta linear modes, the first RF PA **50** does not receive or amplify the first RF input signal FRFI to provide the first RF output signal FRFO.

In one embodiment of the second RF PA **54**, during the first beta non-linear mode and during each of the group of beta linear modes, the second RF PA **54** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO via the single beta PA output SBP. Further, during the first alpha non-linear mode and during each of the group of alpha linear modes, the second RF PA **54** does not receive or amplify the second RF input signal SRFI to provide the second RF output signal SRFO.

In one embodiment of the alpha switching circuitry **52**, during the first alpha non-linear mode, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide the first alpha RF transmit signal FATX via the first alpha harmonic filter **70** and the first alpha output. During each of the group of alpha linear modes, the alpha switching circuitry **52** receives and forwards the first RF output signal FRFO to provide a corresponding one of a group of alpha RF transmit signals TATX, PATX via a corresponding one of the group of alpha outputs.

In one embodiment of the beta switching circuitry **56**, during the first beta non-linear mode, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide the first beta RF transmit signal FBTX via the first beta harmonic filter **74** and the first beta output. During each of the group of beta linear modes, the beta switching circuitry **56** receives and forwards the second RF output signal SRFO to provide a corresponding one of a group of beta RF transmit signals TBTX, QBTX via a corresponding one of the group of beta outputs.

FIG. **39** shows details of the RF PA circuitry **30** illustrated in FIG. **5** according to an additional embodiment of the RF PA circuitry **30**. The RF PA circuitry **30** illustrated in FIG. **39** is similar to the RF PA circuitry **30** illustrated in FIG. **37**, except the RF PA circuitry **30** illustrated in FIG. **39** further includes the switch driver circuitry **98** (FIG. **13**) and shows details of the alpha RF switch **68** and the beta RF switch **72**. The alpha RF switch **68** includes a first alpha switching device **240**, a second alpha switching device **242**, and a third alpha switching device **244**. The beta RF switch **72** includes a first beta switching device **246**, a second beta switching device **248**, and a third beta switching device **250**. Alternate embodiments of the alpha RF switch **68** may include any number of alpha switching devices. Alternate embodiments of the beta RF switch **72** may include any number of beta switching devices.

The first alpha switching device **240** is coupled between the single alpha PA output SAP and the first alpha harmonic filter **70**. As such, the first alpha switching device **240** is coupled between the single alpha PA output SAP and the first alpha non-linear mode output FANO via the first alpha harmonic filter **70**. The second alpha switching device **242** is coupled between the single alpha PA output SAP and the first alpha linear mode output FALO. The third alpha switching device **244** is coupled between the single alpha PA output SAP and the R^{TH} alpha linear mode output RALO. In general, the alpha RF switch **68** includes the first alpha switching device **240** and a group of alpha switching devices, which includes the second alpha switching device **242** and the third alpha switching device **244**. As previously mentioned, the alpha switching circuitry **52** includes the group of alpha linear mode outputs FALO, RALO. As such, each of the group of alpha switching devices **242**, **244** is coupled between the single alpha PA output SAP and a corresponding one of the group of alpha linear mode outputs FALO, RALO. Additionally, each of the alpha switching devices **240**, **242**, **244** has a corresponding control input, which is coupled to the switch driver circuitry **98**.

The first beta switching device **246** is coupled between the single beta PA output SBP and the first beta harmonic filter **74**. As such, the first beta switching device **246** is coupled between the single beta PA output SBP and the first beta non-linear mode output FBNO via the first beta harmonic filter **74**. The second beta switching device **248** is coupled between the single beta PA output SBP and the first beta linear mode output FBLO. The third beta switching device **250** is coupled between the single beta PA output SBP and the S^{TH} beta linear mode output SBLO. In general, the beta RF switch **72** includes the first beta switching device **246** and a group of beta switching devices, which includes the second beta switching device **248** and the third beta switching device **250**. As previously mentioned, the beta switching circuitry **56** includes the group of beta linear mode outputs FBLO, SBLO. As such, each of the group of beta switching devices **248**, **250** is coupled between the single beta PA output SBP and a corresponding one of the group of beta linear mode outputs FBLO, SBLO. Additionally, each of the beta switching devices **246**, **248**, **250** has a corresponding control input, which is coupled to the switch driver circuitry **98**.

In one embodiment of the alpha RF switch **68**, the first alpha switching device **240** includes multiple switching elements (not shown) coupled in series. Each of the group of alpha switching devices **242**, **244** includes multiple switching elements (not shown) coupled in series. In one embodiment of the beta RF switch **72**, the first beta switching device **246** includes multiple switching elements (not shown) coupled in series. Each of the group of beta switching devices **248**, **250** includes multiple switching elements (not shown) coupled in series.

PA Bias Supply Using Boosted Voltage

A summary of a PA bias supply using boosted voltage is presented, followed by a detailed description of the PA bias supply using boosted voltage according to one embodiment of the present disclosure. An RF PA bias power supply signal is provided to RF PA circuitry by boosting a voltage from a DC power supply, such as a battery. In this regard, a DC-DC converter receives a DC power supply signal from the DC power supply. The DC-DC converter provides the bias power supply signal based on the DC power supply signal, such that a voltage of the bias power supply signal is greater than a voltage of the DC power supply signal. The RF PA circuitry has an RF PA, which has a final stage that receives a final bias signal to bias the final stage, such that the final bias signal is based on the bias power supply signal. Boosting the voltage from the DC power supply may provide greater flexibility in biasing the RF PA.

In one embodiment of the DC-DC converter, the DC-DC converter includes a charge pump, which may receive and pump-up the DC power supply signal to provide the bias power supply signal. Further, the DC-DC converter may operate in one of a bias supply pump-up operating mode and at least one other operating mode, which may include any or all of a bias supply pump-even operating mode, a bias supply pump-down operating mode, and a bias supply bypass operating mode. Additionally, the DC-DC converter provides an envelope power supply signal to the RF PA, which uses the envelope power supply signal to provide power for amplification. In one embodiment of the RF PA circuitry, the RF PA circuitry includes PA bias circuitry, which receives the bias power supply signal to provide the final bias signal. The PA bias circuitry may include a final stage current analog-to-digital converter (IDAC) to receive and use the bias power supply signal in a digital-to-analog conversion to provide the final bias signal.

In an alternate embodiment of the RF PA circuitry, the RF PA circuitry includes a first RF PA and a second RF PA, which include a first final stage and a second final stage, respectively. The first RF PA may be used to receive and amplify a highband RF input signal and the second RF PA may be used to receive and amplify a lowband RF input signal. The RF PA circuitry operates in one of a first PA operating mode and a second PA operating mode, such that during the first PA operating mode, the first RF PA is active and the second RF PA is disabled. Conversely, during the second PA operating mode, the first RF PA is disabled and the second RF PA is active. The PA bias circuitry may include the final stage IDAC and a final stage multiplexer. The final stage IDAC receives and uses the bias power supply signal in a digital-to-analog conversion to provide a final stage bias signal to the final stage multiplexer. During the first PA operating mode, the final stage multiplexer receives and forwards the final stage bias signal to provide a first final bias signal to the first RF PA to bias the first final stage. During the second PA operating mode, the final stage multiplexer receives and forwards the final stage bias signal to provide a second final bias signal to the second RF PA to bias the second final stage.

FIG. **40** shows details of the first RF PA **50**, the second RF PA **54**, and the PA bias circuitry **96** illustrated in FIG. **13** according to one embodiment of the first RF PA **50**, the second RF PA **54**, and the PA bias circuitry **96**. The first RF PA **50** includes a first driver stage **252** and a first final stage **254**. The second RF PA **54** includes a second driver stage **256** and a second final stage **258**. The PA bias circuitry **96** includes driver stage IDAC circuitry **260** and final stage IDAC circuitry **262**. In general, the first RF PA **50** receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO. Similarly, the second RF PA **54** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO. Specifically, the first driver stage **252** receives and amplifies the first RF input signal FRFI to provide a first final stage input signal FFSI, and the first final stage **254** receives and amplifies the first final stage input signal FFSI to provide the first RF output signal FRFO. Similarly, the second driver stage **256** receives and amplifies the second RF input signal SRFI to provide a second final stage input signal SFSI, and the second final stage **258** receives and amplifies the second final stage input signal SFSI to provide the second RF output signal SRFO.

The first driver stage **252** receives the envelope power supply signal EPS, which provides power for amplification; the first final stage **254** receives the envelope power supply signal EPS, which provides power for amplification; the second driver stage **256** receives the envelope power supply signal EPS, which provides power for amplification; and the second final stage **258** receives the envelope power supply signal EPS, which provides power for amplification. In general, the first RF PA **50** receives the first driver bias signal FDB to bias first driver stage **252** and receives the first final bias signal FFB to bias the first final stage **254**. Specifically, the first driver stage **252** receives the first driver bias signal FDB to bias the first driver stage **252** and the first final stage **254** receives the first final bias signal FFB to bias the first final stage **254**. Similarly, the second RF PA **54** receives the second driver bias signal SDB to bias the second driver stage **256** and receives the second final bias signal SFB to bias the second final stage **258**. Specifically, the second driver stage **256** receives the second driver bias signal SDB to bias the second driver stage **256** and the second final stage **258** receives the second final bias signal SFB to bias the second final stage **258**.

In general, the PA bias circuitry **96** provides the first driver bias signal FDB based on the bias power supply signal BPS, the first final bias signal FFB based on the bias power supply signal BPS, the second driver bias signal SDB based on the bias power supply signal BPS, and the second final bias signal SFB based on the bias power supply signal BPS. Specifically, the driver stage IDAC circuitry **260** provides the first driver bias signal FDB based on the bias power supply signal BPS and provides the second driver bias signal SDB based on the bias power supply signal BPS. Similarly, the final stage IDAC circuitry **262** provides the first final bias signal FFB based on the bias power supply signal BPS and provides the second final bias signal SFB based on the bias power supply signal BPS.

In one embodiment of the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262**, the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262** receive the bias power supply signal BPS and the bias configuration control signal BCC. The driver stage IDAC circuitry **260** provides the first driver bias signal FDB and the second driver bias signal SDB based on the bias power supply signal BPS and the bias configuration control signal BCC. The final stage IDAC circuitry **262** provides the first final bias signal FFB and the second final bias signal SFB based on the bias power supply signal BPS and the bias configuration control signal BCC. The bias power supply signal BPS provides the power necessary to generate the bias signals FDB, FFB, SDB, SFB. A selected magnitude of each of the bias signals FDB, FFB, SDB, SFB is provided by the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262**. In one embodiment of the RF PA circuitry **30**, the PA control circuitry **94** selects the magnitude of any or all of the bias signals FDB, FFB, SDB, SFB and communicates the magnitude selections to the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262** via the bias configuration control signal BCC. The magnitude selections by the PA control circuitry **94** may be based on the PA configuration control signal PCC. In an alternate embodiment of the RF PA circuitry **30**, the control circuitry **42** (FIG. **5**) selects the magnitude of any or all of the bias signals FDB, FFB, SDB, SFB and communicates the magnitude selections to the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262** via the PA control circuitry **94**.

As previously discussed, in one embodiment of the RF PA circuitry **30**, the RF PA circuitry **30** operates in one of the first PA operating mode and the second PA operating mode. During the first PA operating mode, the first RF PA **50** receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO, and the second RF PA **54** is disabled. During the second PA operating mode, the second RF PA **54** receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO, and the first RF PA **50** is disabled.

In one embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via the first driver bias signal FDB. As such, the first driver stage **252** is disabled. In an alternate embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via the first final bias signal FFB. As such, the first final stage **254** is disabled. In an additional embodiment of the first RF PA **50**, during the second PA operating mode, the first RF PA **50** is disabled via both the first driver bias signal FDB and the first final bias signal FFB. As such, both the first driver stage **252** and the first final stage **254** are disabled.

In one embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via the second driver bias signal SDB. As such, the second driver stage **256** is disabled. In an alternate embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via the second final bias signal SFB. As such, the second final stage **258** is disabled. In an additional embodiment of the second RF PA **54**, during the first PA operating mode, the second RF PA **54** is disabled via both the second driver bias signal SDB and the second final bias signal SFB. As such, both the second driver stage **256** and the second final stage **258** are disabled.

In one embodiment of the RF PA circuitry **30**, the PA control circuitry **94** selects the one of the first PA operating mode and the second PA operating mode. As such, the PA control circuitry **94** may control any or all of the bias signals FDB, FFB, SDB, SFB via the bias configuration control signal BCC based on the PA operating mode selection. The PA operating mode selection may be based on the PA configuration control signal PCC. In an alternate embodiment of the RF PA circuitry **30**, the control circuitry **42** (FIG. **5**) selects the one of the first PA operating mode and the second PA operating mode. As such, the control circuitry **42** (FIG. **5**) may indicate the operating mode selection to the PA control circuitry **94** via the PA configuration control signal PCC. In an additional embodiment of the RF PA circuitry **30**, the RF modulation and control circuitry **28** (FIG. **5**) selects the one of the first PA operating mode and the second PA operating mode. As such, the RF modulation and control circuitry **28** (FIG. **5**) may indicate the operating mode selection to the PA control circuitry **94** via the PA configuration control signal PCC. In general, selection of the PA operating mode is made by control circuitry, which may be any of the PA control circuitry **94**, the RF modulation and control circuitry **28** (FIG. **5**), and the control circuitry **42** (FIG. **5**).

Further, during the first PA operating mode, the control circuitry selects a desired magnitude of the first driver bias signal FDB, a desired magnitude of the first final bias signal FFB, or both. During the second PA operating mode, the control circuitry selects a desired magnitude of the second driver bias signal SDB, a desired magnitude of the second final bias signal SFB, or both As such, during the first PA operating mode, the PA control circuitry **94** provides the bias configuration control signal BCC to the PA bias circuitry **96** in general and to the driver stage IDAC circuitry **260** in particular based on the desired magnitude of the first driver bias signal FDB, and the PA control circuitry **94** provides the bias configuration control signal BCC to the PA bias circuitry **96** in general and to the final stage IDAC circuitry **262** in particular based on the desired magnitude of the first final bias signal FFB. During the second PA operating mode, the PA control circuitry **94** provides the bias configuration control signal BCC to the PA bias circuitry **96** in general and to the driver stage IDAC circuitry **260** in particular based on the desired magnitude of the second driver bias signal SDB, and the PA control circuitry **94** provides the bias configuration control signal BCC to the PA bias circuitry **96** in general and to the final stage IDAC circuitry **262** in particular based on the desired magnitude of the second final bias signal SFB. In one embodiment of the PA control circuitry **94**, the bias configuration control signal BCC is a digital signal.

FIG. **41** shows details of the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262** illustrated in FIG. **40** according to one embodiment of the driver stage IDAC circuitry **260** and the final stage IDAC circuitry **262**. The driver stage IDAC circuitry **260** includes a driver stage IDAC **264**, a driver stage multiplexer **266**, and driver stage current reference circuitry **268**. The final stage IDAC circuitry **262** includes a final stage IDAC **270**, a final stage multiplexer **272**, and final stage current reference circuitry **274**.

The driver stage IDAC **264** receives the bias power supply signal BPS, the bias configuration control signal BCC, and a driver stage reference current IDSR. As such, the driver stage IDAC **264** uses the bias power supply signal BPS and the driver stage reference current IDSR in a digital-to-analog conversion to provide a driver stage bias signal DSBS. A magnitude of the digital-to-analog conversion is based on the bias configuration control signal BCC. The driver stage current reference circuitry **268** is coupled to the driver stage IDAC **264** and provides the driver stage reference current IDSR to the driver stage IDAC **264**, such that during the first PA operating mode, the first driver bias signal FDB is based on the driver stage reference current IDSR, and during the second PA operating mode, the second driver bias signal SDB is based on the driver stage reference current IDSR. The driver stage current reference circuitry **268** may be disabled based on the bias configuration control signal BCC. The driver stage current reference circuitry **268** and the driver stage multiplexer **266** receive the bias configuration control signal BCC. The driver stage multiplexer **266** receives and forwards the driver stage bias signal DSBS, which is a current signal, to provide either the second driver bias signal SDB or the first driver bias signal FDB based on the bias configuration control signal BCC. During the first PA operating mode, the driver stage multiplexer **266** receives and forwards the driver stage bias signal DSBS to provide the first driver bias signal FDB based on the bias configuration control signal BCC. During the second PA operating mode, the driver stage multiplexer **266** receives and forwards the driver stage bias signal DSBS to provide the second driver bias signal SDB based on the bias configuration control signal BCC.

In this regard, during the first PA operating mode, the driver stage IDAC **264** provides the first driver bias signal FDB via the driver stage multiplexer **266**, such that a magnitude of the first driver bias signal FDB is about equal to the desired magnitude of the first driver bias signal FDB. During the second PA operating mode, the driver stage IDAC **264** provides the second driver bias signal SDB via the driver stage multiplexer **266**, such that a magnitude of the second driver bias signal SDB is about equal to the desired magnitude of the second driver bias signal SDB.

In one embodiment of the driver stage multiplexer **266**, during the first PA operating mode, the driver stage multiplexer **266** disables the second RF PA **54** via the second driver bias signal SDB. In one embodiment of the second RF PA **54**, the second RF PA **54** is disabled when the second driver bias signal SDB is about zero volts. In one embodiment of the driver stage multiplexer **266**, during the second PA operating mode, the driver stage multiplexer **266** disables the first RF PA **50** via the first driver bias signal FDB. In one embodiment of the first RF PA **50**, the first RF PA **50** is disabled when the first driver bias signal FDB is about zero volts. As such, in one embodiment of the driver stage multiplexer **266**, during the first PA operating mode, the driver stage multiplexer **266** provides the second driver bias signal SDB, which is about zero volts, such that the second RF PA **54** is disabled, and during the second PA operating mode, the driver stage multiplexer **266** provides the first driver bias signal FDB, which is about zero volts, such that the first RF PA **50** is disabled.

The final stage IDAC **270** receives the bias power supply signal BPS, the bias configuration control signal BCC, and a final stage reference current IFSR. As such, the final stage IDAC **270** uses the bias power supply signal BPS and the final stage reference current IFSR in a digital-to-analog conversion to provide a final stage bias signal FSBS. A magnitude of the digital-to-analog conversion is based on the bias configuration control signal BCC. The final stage current reference circuitry **274** is coupled to the final stage IDAC **270** and provides the final stage reference current IFSR to the final stage IDAC **270**, such that during the first PA operating mode, the first final bias signal FFB is based on the final stage reference current IFSR, and during the second PA operating mode, the second final bias signal SFB is based on the final stage reference current IFSR. The final stage current reference circuitry **274** and the final stage IDAC **270** receive the bias configuration control signal BCC. The final stage current reference circuitry **274** may be disabled based on the bias configuration control signal BCC. The final stage multiplexer **272** receives and forwards the final stage bias signal FSBS, which is a current signal, to provide either the second final bias signal SFB or the first final bias signal FFB based on the bias configuration control signal BCC. During the first PA operating mode, the final stage multiplexer **272** receives and forwards the final stage bias signal FSBS to provide the first final bias signal FFB based on the bias configuration control signal BCC. During the second PA operating mode, the final stage multiplexer **272** receives and forwards the final stage bias signal FSBS to provide the second final bias signal SFB based on the bias configuration control signal BCC.

In this regard, during the first PA operating mode, the final stage IDAC **270** provides the first final bias signal FFB via the final stage multiplexer **272**, such that a magnitude of the first final bias signal FFB is about equal to the desired magnitude of the first final bias signal FFB. Specifically, the final stage IDAC **270** receives and uses the bias power supply signal BPS and the bias configuration control signal BCC in a digital-to-analog conversion to provide the first final bias signal FFB. During the second PA operating mode, the final stage IDAC **270** provides the second final bias signal SFB via the final stage multiplexer **272**, such that a magnitude of the second final bias signal SFB is about equal to the desired magnitude of the second final bias signal SFB. Specifically, the final stage IDAC **270** receives and uses the bias power supply signal BPS and the bias configuration control signal BCC in a digital-to-analog conversion to provide the second final bias signal SFB.

In one embodiment of the final stage multiplexer **272**, during the first PA operating mode, the final stage multiplexer **272** disables the second RF PA **54** via the second final bias signal SFB. In one embodiment of the second RF PA **54**, the second RF PA **54** is disabled when the second final bias signal SFB is about zero volts. In one embodiment of the final stage multiplexer **272**, during the second PA operating mode, the final stage multiplexer **272** disables the first RF PA **50** via the first final bias signal FFB. In one embodiment of the first RF PA **50**, the first RF PA **50** is disabled when the first final bias signal FFB is about zero volts. As such, in one embodiment of the final stage multiplexer **272**, during the first PA operating mode, the final stage multiplexer **272** provides the second final bias signal SFB, which is about zero volts, such that the second RF PA **54** is disabled, and during the second PA operating mode, the final stage multiplexer **272** provides the first final bias signal FFB, which is about zero volts, such that the first RF PA **50** is disabled.

FIG. **42** shows details of the driver stage current reference circuitry **268** and the final stage current reference circuitry **274** illustrated in FIG. **41** according to one embodiment of the driver stage current reference circuitry **268** and the final stage current reference circuitry **274**. The driver stage current reference circuitry **268** includes a driver stage temperature compensation circuit **276** to temperature compensate the driver stage reference current IDSR. The final stage current reference circuitry **274** includes a final stage temperature compensation circuit **278** to temperature compensate the final stage reference current IFSR.

Charge Pump Based PA Envelope Power Supply and Bias Power Supply

A summary of a charge pump based PA envelope power supply and bias power supply is presented, followed by a detailed description of the charge pump based PA envelope power supply according to one embodiment of the present disclosure. The present disclosure relates to a DC-DC converter, which includes a charge pump based RF PA envelope power supply and a charge pump based PA bias power supply. The DC-DC converter is coupled between RF PA circuitry and a DC power supply, such as a battery. As such, the PA envelope power supply provides an envelope power supply signal to the RF PA circuitry and the PA bias power supply provides a bias power supply signal to the RF PA circuitry. Both the PA envelope power supply and the PA bias power supply receive power via a DC power supply signal from the DC power supply. The PA envelope power supply includes a charge pump buck converter and the PA bias power supply includes a charge pump.

By using charge pumps, a voltage of the envelope power supply signal may be greater than a voltage of the DC power supply signal, a voltage of the bias power supply signal may be greater than the voltage of the DC power supply signal, or both. Providing boosted voltages may provide greater flexibility in providing envelope power for amplification and in biasing the RF PA circuitry. The charge pump buck converter provides the functionality of a charge pump feeding a buck converter. However, the charge pump buck converter requires fewer switching elements than a charge pump feeding a buck converter by sharing certain switching elements.

The charge pump buck converter is coupled between the DC power supply and the RF PA circuitry. The charge pump is coupled between the DC power supply and the RF PA circuitry. In one embodiment of the PA envelope power supply, the PA envelope power supply further includes a buck converter coupled between the DC power supply and the RF PA circuitry. The PA envelope power supply may operate in one of a first envelope operating mode and a second envelope operating mode. During the first envelope operating mode, the charge pump buck converter is active, and the buck converter is inactive. Conversely, during the second envelope operating mode, the charge pump buck converter is inactive, and the buck converter is active. As such, the PA envelope power supply may operate in the first envelope operating mode when a voltage above the voltage of the DC power supply signal may be needed. Conversely, the PA envelope power supply may operate in the second envelope operating mode when a voltage above the voltage of the DC power supply signal is not needed.

In one embodiment of the charge pump buck converter, the charge pump buck converter operates in one of a pump buck pump-up operating mode and at least one other pump buck operating mode, which may include any or all of a pump buck pump-down operating mode, a pump buck pump-even operating mode, and a pump buck bypass operating mode. In one embodiment of the charge pump, the charge pump operates in one of a bias supply pump-up operating mode and at least one other bias supply operating mode, which may include any or all of a bias supply pump-down operating mode, a bias supply pump-even operating mode, and a bias supply bypass operating mode.

In one embodiment of the RF PA circuitry, the RF PA circuitry has an RF PA, which is biased based on the bias power supply signal and receives the envelope power supply signal to provide power for amplification.

In one embodiment of the RF PA circuitry, the RF PA has a final stage that receives a final bias signal to bias the final stage, such that the final bias signal is based on the bias power supply signal. Additionally, the DC-DC converter provides the envelope power supply signal to the RF PA, which uses the envelope power supply signal to provide power for amplification. In one embodiment of the RF PA circuitry, the RF PA circuitry includes PA bias circuitry, which receives the bias power supply signal to provide the final bias signal. In one embodiment of the PA bias circuitry, the PA bias circuitry includes a final stage IDAC to receive and use the bias power supply signal in a digital-to-analog conversion to provide the final bias signal.

In one embodiment of the RF PA circuitry, the RF PA circuitry includes a first RF PA and a second RF PA, which may include a first final stage and a second final stage, respectively. The first RF PA is used to receive and amplify a highband RF input signal and the second RF PA is used to receive and amplify a lowband RF input signal. The RF PA circuitry may operate in one of a first PA operating mode and a second PA operating mode, such that during the first PA operating mode, the first RF PA is active and the second RF PA is disabled. Conversely, during the second PA operating mode, the first RF PA is disabled and the second RF PA is active. The PA bias circuitry includes the final stage IDAC and a final stage multiplexer. The final stage IDAC receives and uses the bias power supply signal in a digital-to-analog conversion to provide a final stage bias signal to the final stage multiplexer. During the first PA operating mode, the final stage multiplexer receives and forwards the final stage bias signal to provide a first final bias signal to the first RF PA to bias the first final stage. During the second PA operating mode, the final stage multiplexer receives and forwards the final stage bias signal to provide a second final bias signal to the second RF PA to bias the second final stage.

Interference Reduction Between RF Communications Bands

Embodiments of the present disclosure relate to RF PA circuitry and a PA envelope power supply. The RF PA circuitry receives and amplifies an RF input signal to provide an RF output signal using an envelope power supply signal, which is provided by the PA envelope power supply. The RF PA circuitry operates in either a normal RF spectral emissions mode or a reduced RF spectral emissions mode. When reduced RF spectral emissions are required, the RF PA circuitry operates in the reduced RF spectral emissions mode. As such, at a given RF output power, during the reduced RF spectral emissions mode, RF spectral emissions of the RF output signal are less than during the normal RF spectral emissions mode. As a result, the reduced RF spectral emissions mode may be used to reduce interference between RF communications bands.

Cellular communications bands are often adjacent to non-cellular communications bands. As such, interference between the cellular communications bands and the non-cellular communications bands needs to be minimized for the corresponding cellular and the non-cellular systems to operate properly and efficiently. For example, RF emissions from cellular communications signals that bleed into a non-cellular communications band must be low enough to prevent problems in the corresponding non-cellular communications system. Such RF emissions may be called RF spectral emissions since these emissions fall outside of a desired RF spectrum associated with a corresponding cellular communications signal.

The RF spectral emissions from a cellular communications signal may adversely impact the non-cellular communications system. However, when the cellular communications band is adequately separated from the non-cellular communications band, when a magnitude of the cellular communications signal having RF spectral emissions is sufficiently small, when a sensitivity of the corresponding non-cellular communications system to the RF spectral emissions is sufficiently small, or any combination thereof, the cellular communications signal does not adversely impact the non-cellular communications system.

In this regard, when the cellular communications band is about adjacent to the non-cellular communications band and the non-cellular communications system is sensitive to the RF spectral emissions, the RF spectral emissions must be limited to allow the non-cellular communications system to function properly. As such, the RF spectral emissions may be limited by limiting the magnitude of the cellular communications signal, by reducing characteristic RF spectral emissions of the cellular communications signal, or both. The characteristic RF spectral emissions may be reduced by increasing linearity in an RF PA, by improving a quadrature balance of a quadrature RF PA, or both.

As previously mentioned, the DC-DC converter **32** (FIG. **2**) provides the envelope power supply signal EPS to the RF PA circuitry **30** (FIG. **2**). The RF PA circuitry **30** (FIG. **14**) includes the PA-DCI **60** (FIG. **14**), the PA control circuitry **94** (FIG. **14**), the first RF PA **50** (FIG. **14**), and the second RF PA **54** (FIG. **14**). The PA-DCI **60** (FIG. **14**) is coupled between the PA control circuitry **94** (FIG. **14**) and the digital communications bus **66** (FIG. **14**). The DC-DC converter **32** (FIG. **2**) provides the envelope power supply signal EPS to the first RF PA **50** (FIG. **14**) and to the second RF PA **54** (FIG. **14**). The PA bias circuitry **96** (FIG. **14**) provides the first driver bias signal FDB and the first final bias signal FFB to the first RF PA **50** (FIG. **14**) based on the bias power supply signal BPS and the bias configuration control signal BCC. The PA bias circuitry **96** (FIG. **14**) provides the second driver bias signal SDB and the second final bias signal SFB to the second RF PA **54** (FIG. **14**) based on the bias power supply signal BPS and the bias configuration control signal BCC. As such, the PA bias circuitry **96** (FIG. **14**) is coupled between the PA control circuitry **94** (FIG. **14**) and the RF PAs **50**, **54** (FIG. **14**).

The first RF PA **50** (FIG. **14**) receives and amplifies the first RF input signal FRFI to provide the first RF output signal FRFO using the envelope power supply signal EPS. The second RF PA **54** (FIG. **14**) receives and amplifies the second RF input signal SRFI to provide the second RF output signal SRFO using the envelope power supply signal EPS. In general, the RF PA circuitry **30** (FIG. **14**) receives and amplifies an RF input signal to provide an RF output signal using the envelope power supply signal EPS (FIG. **14**). Further, in general, the RF PA circuitry **30** (FIG. **14**) includes an RF PA, which receives and amplifies the RF input signal to provide the RF output signal using the envelope power supply signal EPS. In one embodiment of the RF PA, the RF PA is a quadrature RF PA, which receives and amplifies the RF input signal to provide the RF output signal using the envelope power supply signal EPS. In this regard, the PA bias circuitry **96** (FIG. **14**) is coupled between the PA control circuitry **94** (FIG. **14**) and the RF PAs.

In a first embodiment of the RF PA circuitry **30** (FIG. **14**), the RF PA is the first RF PA **50** (FIG. **14**), the RF input signal is the first RF input signal FRFI and the RF output signal is the first RF output signal FRFO. In a second embodiment of the RF PA circuitry **30** (FIG. **14**), the RF PA is the second RF PA **54** (FIG. **14**), the RF input signal is the second RF input signal SRFI and the RF output signal is the second RF output signal SRFO.

In one embodiment of the RF PA circuitry **30** (FIG. **40**), the first RF PA **50** (FIG. **40**) includes the first driver stage **252** (FIG. **40**) and the first final stage **254** (FIG. **40**). The second RF PA **54** (FIG. **40**) includes the second driver stage **256** (FIG. **40**) and the second final stage **258** (FIG. **40**). In one embodiment of the RF PA, the RF PA includes a driver stage and a final stage. In an exemplary embodiment of the RF PA, the driver stage is the first driver stage **252** (FIG. **40**) and the final stage is the first final stage **254** (FIG. **40**). In an alternate exemplary embodiment of the RF PA, the driver stage is the second driver stage **256** (FIG. **40**) and the final stage is the second final stage **258** (FIG. **40**). In one embodiment of the quadrature RF PA, the RF PA includes a quadrature driver stage and a quadrature final stage. In an exemplary embodiment of the quadrature RF PA, the quadrature driver stage is the first driver stage **252** (FIG. **40**) and the quadrature final stage is the first final stage **254** (FIG. **40**). In an alternate exemplary embodiment of the quadrature RF PA, the quadrature driver stage is the second driver stage **256** (FIG. **40**) and the quadrature final stage is the second final stage **258** (FIG. **40**).

In one embodiment of the RF PA circuitry **30** (FIG. **14**), the RF PA circuitry **30** (FIG. **14**) operates in one of a normal RF spectral emissions mode and a reduced RF spectral emissions mode. When reduced RF spectral emissions are required, the RF PA circuitry **30** (FIG. **14**) operates in the reduced RF spectral emissions mode. At a given RF output power, during the reduced RF spectral emissions mode, RF spectral emissions of the RF output signal are less than during the normal RF spectral emissions mode.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), when reduced RF spectral emissions are not required, the RF PA circuitry **30** (FIG. **14**) operates in the normal RF spectral emissions mode. In an alternate embodiment of the RF PA circuitry **30** (FIG. **14**), the RF PA circuitry **30** (FIG. **14**) is hardwired to select the reduced RF spectral emissions mode, such that the reduced RF spectral emissions mode is continuously selected. In an additional embodiment of the RF PA circuitry **30** (FIG. **14**), the PA control circuitry **94** (FIG. **14**) selects the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), the RF output signal falls within one of a group of RF communications bands, such that the group of RF communications bands includes a first RF communications band, which is about adjacent to a second RF communications band. In one embodiment of the RF PA circuitry **30** (FIG. **14**), when the one of the group of RF communications bands is the first RF communications band, reduced RF spectral emissions are required. In an alternate embodiment of the RF PA circuitry **30** (FIG. **14**), when the one of the group of RF communications bands is the first RF communications band and an RF output power from the RF PA is higher than an RF output power threshold, reduced RF spectral emissions are required.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), the first RF communications band is a cellular communications band and the second RF communications band is a non-cellular communications band. In one embodiment of the first RF communications band, the first RF communications band is a 3rd Generation Partnership Project (3GPP) cellular communications band. In one embodiment of the 3GPP cellular communications band, the 3GPP cellular communications band is a 3GPP long term evolution (3GPP-LTE) cellular communications band. In one embodiment of the first RF communications band, a frequency range of the first RF communications band is between about 777 megahertz and about 787 megahertz. In one embodiment of the second RF communications band, the second RF communications band is a Public Safety Band, which is a non-cellular communications band. In one embodiment of the second RF communications band, a frequency range of the second RF communications band is between about 788 megahertz and about 798 megahertz.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, the RF PA has higher PA linearity than during the normal RF spectral emissions mode. As such, to provide higher linearity, in one embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, the RF PA has a higher PA bias level than during the normal RF spectral emissions mode. Further, to provide higher linearity, in one embodiment of the RF PA circuitry **30** (FIG. **14**), at a given RF output power, during the reduced RF spectral emissions mode, a magnitude of the envelope power supply signal EPS (FIG. **14**) is higher than during the normal RF spectral emissions mode.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, a quadrature balance of the quadrature RF PA is better than during the normal RF spectral emissions mode. The quadrature balance is better when a signal level in an in-phase path of the quadrature RF PA is closer to matching a signal level in a quadrature-phase path of the quadrature RF PA. In an alternate embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, a quadrature balance of the quadrature RF PA is better and the quadrature RF PA has higher PA linearity than during the normal RF spectral emissions mode.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, a quadrature balance of the quadrature final stage is better than during the normal RF spectral emissions mode. In one embodiment of the quadrature final stage, during the reduced RF spectral emissions mode, a bias level of the quadrature final stage is different than during the normal RF spectral emissions mode to improve quadrature balance of the quadrature final stage.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, a quadrature balance of the quadrature driver stage is better than during the normal RF spectral emissions mode. In one embodiment of the quadrature driver stage, during the reduced RF spectral emissions mode, a bias level of the quadrature driver stage is different than during the normal RF spectral emissions mode to improve quadrature balance of the quadrature driver stage.

In an alternate embodiment of the RF PA circuitry **30** (FIG. **14**), during the reduced RF spectral emissions mode, a quadrature balance of the quadrature final stage is better and a quadrature balance of the quadrature driver stage is better than during the normal RF spectral emissions mode. In one embodiment of the quadrature final stage and the quadrature driver stage, during the reduced RF spectral emissions mode, a bias level of the quadrature final stage is different and a bias level of the quadrature driver stage is different than during the normal RF spectral emissions mode to improve quadrature balance of the quadrature final stage and the quadrature driver stage.

In one embodiment of the RF PA circuitry **30** (FIG. **14**), the PA control circuitry **94** (FIG. **14**) receives information via the digital communications bus **66** (FIG. **14**) and selects the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode based on the information. In one embodiment of the RF PA circuitry **30** (FIG. **14**), the RF output signal falls within one of the group of RF communications bands and the information identifies the one of the group of RF communications bands. In one embodiment of the RF PA circuitry **30** (FIG. **14**), the information is indicative of the RF output power from the RF PAs. In one embodiment of the RF PA circuitry **30** (FIG. **14**), the information is indicative of the magnitude of the envelope power supply signal EPS (FIG. **14**). In this regard, in one embodiment of the RF PA circuitry **30** (FIG. **14**), the PA control circuitry **94** (FIG. **14**) selects the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode based on the one of the group of RF communications bands, the indicated RF output power from the RF PAs, the indicated magnitude of the envelope power supply signal EPS (FIG. **14**), or any combination thereof.

In one embodiment of the transceiver circuitry **34** (FIG. **6**), the transceiver circuitry **34** (FIG. **6**) provides the information to the PA control circuitry **94** (FIG. **14**) via the digital communications bus **66** (FIG. **14**). In one embodiment of the transceiver circuitry **34** (FIG. **6**), the transceiver circuitry **34** (FIG. **6**) selects the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode and indicates the selection via the information. In one embodiment of the RF communications system **26** (FIG. **6**), the RF communications system **26** (FIG. **6**) receives RF signals that are used by the transceiver circuitry **34** (FIG. **6**) to provide the information. The RF communications system **26** (FIG. **6**) may be part of a communications network and the received RF signals may be indicative of network commands, network information, or the like, which are used by the transceiver circuitry **34** (FIG. **6**) to provide the information.

Those skilled in the art will recognize improvements and modifications to the preferred embodiments of the present disclosure. All such improvements and modifications are considered within the scope of the concepts disclosed herein and the claims that follow.

What is claimed is:

1. Circuitry comprising:

radio frequency (RF) power amplifier (PA) circuitry comprising a quadrature RF PA and adapted to:

receive and amplify an RF input signal using the quadrature RF PA to provide an RF output signal using an envelope power supply signal;

operate in one of a normal RF spectral emissions mode and a reduced RF spectral emissions mode, wherein a quadrature balance of the quadrature RF PA is better in the reduced RF spectral emissions mode than in the normal RF spectral emissions mode;

when reduced RF spectral emissions are required, operate in the reduced RF spectral emissions mode, such that the quadrature RF PA has higher PA linearity in the reduced RF spectral emissions mode than during the normal RF spectral emissions mode; and

when reduced RF spectral emissions are not required, operate in the normal RF spectral emissions mode; and

a PA envelope power supply adapted to provide the envelope power supply signal.

2. The circuitry of claim **1** wherein when the reduced RF spectral emissions are not required, the RF PA circuitry is further adapted to operate in the normal RF spectral emissions mode.

3. The circuitry of claim **1** wherein at a given RF output power, during the reduced RF spectral emissions mode, RF spectral emissions of the RF output signal are less than during the normal RF spectral emissions mode.

4. The circuitry of claim **1** wherein:

the RF output signal falls within one of a plurality of RF communications bands;

the plurality of RF communications bands comprises a first RF communications band, which is about adjacent to a second RF communications band; and

when the one of the plurality of RF communications bands is the first RF communications band, reduced RF spectral emissions are required.

5. The circuitry of claim **1** wherein:

the RF output signal falls within one of a plurality of RF communications bands;

the plurality of RF communications bands comprises a first RF communications band, which is about adjacent to a second RF communications band; and

when the one of the plurality of RF communications bands is the first RF communications band and an RF output power from the quadrature RF PA is higher than an RF output power threshold, reduced RF spectral emissions are required.

6. The circuitry of claim **5** wherein the first RF communications band is a cellular communications band and the second RF communications band is a non-cellular communications band.

7. The circuitry of claim **6** wherein the first RF communications band is a 3rd Generation Partnership Project (3GPP) cellular communications band and the second RF communications band is a Public Safety Band.

8. The circuitry of claim **7** wherein a frequency range of the first RF communications band is between about 777 megahertz and about 787 megahertz, and a frequency range of the second RF communications band is between about 788 megahertz and about 798 megahertz.

9. The circuitry of claim **1** wherein at a given RF output power, during the reduced RF spectral emission mode, a magnitude of the envelope power supply signal is higher than during the normal RF spectral emissions mode.

10. The circuitry of claim **1** wherein:

the quadrature RF PA comprises a quadrature final stage; and

during the reduced RF spectral emissions mode, a bias level of the quadrature final stage is different than during the normal RF spectral emissions mode to improve a quadrature balance of the quadrature final stage.

11. The circuitry of claim **10** wherein:

the quadrature RF PA comprises a quadrature driver stage; and

during the reduced RF spectral emissions mode, a bias level of the quadrature driver stage is different than during the normal RF spectral emissions mode to improve a quadrature balance of the quadrature driver stage.

12. The circuitry of claim **1** wherein:

the quadrature RF PA comprises a quadrature driver stage; and

during the reduced RF spectral emissions mode, a bias level of the quadrature driver stage is different than during the normal RF spectral emissions mode to improve a quadrature balance of the quadrature driver stage.

13. The circuitry of claim **1** wherein the RF PA circuitry is hardwired to select the reduced RF spectral emissions mode.

14. The circuitry of claim **1** wherein the RF PA circuitry comprises:

the quadrature RF PA adapted to receive and amplify the RF input signal to provide the RF output signal using the envelope power supply signal;

PA control circuitry adapted to select the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode; and

PA bias circuitry coupled between the PA control circuitry and the quadrature RF PA.

15. The circuitry of claim **14** wherein:

the RF PA circuitry further comprises a PA-digital communications interface (PA-DCI) coupled between a digital communications bus and the PA control circuitry; and

the PA control circuitry is further adapted to receive information via the digital communications bus and select the one of the normal RF spectral emissions mode and the reduced RF spectral emissions mode based on the information.

16. The circuitry of claim **15** wherein:

the RF output signal falls within one of a plurality of RF communications bands; and

the information identifies the one of the plurality of RF communications bands.

17. The circuitry of claim **16** wherein the information is indicative of an RF output power from the quadrature RF PA.

18. The circuitry of claim **16** wherein the information is indicative of a magnitude of the envelope power supply signal.

19. A method comprising:

receiving and amplifying a radio frequency (RF) input signal using a quadrature RF power amplifier (PA) to provide an RF output signal using an envelope power supply signal;

operating in one of a normal RF spectral emissions mode and a reduced RF spectral emissions mode;

when reduced RF spectral emissions are required, operating in the reduced RF spectral emissions mode, wherein a quadrature balance of the quadrature RF PA is better in the reduced spectral emissions mode than in the normal RF spectral emissions mode;

when reduced RF spectral emissions are not required, operating in the normal RF spectral emissions mode; and

providing the envelope power supply signal.

(57) **ABSTRACT**

An apparatus for perpetually harvesting ambient near ultraviolet to far infrared radiation to provide continual power regardless of the environment, incorporating a system for the harvesting electronics governing power management, storage control, and output regulation. The harvesting electronics address issues of efficiently matching the voltage and current characteristics of the different harvested energy levels, low power consumption, and matching the power output demand. The device seeks to harvest the largely overlooked blackbody radiation through use of a thermal harvester, providing a continuous source of power, coupled with a solar harvester to provide increased power output.

INTEGRATED ELECTRONICS FOR PERPETUAL ENERGY HARVESTING

PARENT CASE TEXT

This is a divisional of application(s) Ser. No. 13/151,253 filed on Jun. 1, 2011.

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH AND DEVELOPMENT

This invention was made in part with Government support under contract no. W31P4Q10C0034 awarded by US Army Aviation and Missile Command. The Government has certain rights in the invention.

CROSS-REFERENCE TO RELATED APPLICATIONS

Not Applicable

FIELD OF INVENTION

This invention pertains to the harvesting of ambient energy in the surrounding, environment. More particularly this invention is related to a semiconductor perpetual energy harvesting and storage device and the harvesting electronics that control energy storage and output allowing the device to continually harvest and provide continuous power during both day and night in any environment.

BACKGROUND OF INVENTION

There are many sources of energy that can be converted into electrical energy. Sources that have been explored for harvesting are wind, temperature differences, motion, light energy and radio frequency energy. In all these energy situations, a specific situation must be present, such as air flow, temperature gradient, movement, sunlight, or transmitted RF, before energy can be harvested. When these situations do not occur, there is no source for energy to be harvested.

Harvesting ambient thermal energy has not been widely explored. The characteristic of thermal energy having a peak at long infrared wavelengths poses a significant challenge for harvesting. Additionally, power management, storage control, and regulation electronics must be developed to operate efficiently and respond to the power output demand.

BRIEF DESCRIPTION OF DRAWINGS

FIGS. **1**A and B depicts a high level structural representation of an energy harvesting system.

FIG. **2** depicts power available from blackbody radiation at various temperatures

FIG. **3** depicts the discharge characteristics of a lithium ion battery.

FIG. **4** depicts a block diagram of the harvester electronics utilizing a dual circuit design.

FIG. **5** depicts an alternate embodiment of a block diagram of the harvester electronics utilizing a dual circuit design.

FIG. **6** depicts a block diagram of the harvester electronics utilizing a single circuit design.

FIG. **7** depicts an alternate embodiment of a block diagram of the harvester electronics utilizing a single circuit design.

DETAILED DESCRIPTION

Reference is made in detail to the preferred embodiments of the invention. While the invention is described in conjunction with the preferred embodiments, the invention is not intended to be limited by these preferred embodiments. The contemplated embodiments for carrying out the present invention are described in turn with reference to the accompanying figures.

For purposes of the invention, radiation is defined to be the electromagnetic spectrum, particularly the near ultraviolet, visible, near infrared, short-wave infrared, mid-wave infrared, long-wave infrared and far infrared bands. The near ultraviolet hand is comprised of wavelengths from about 300 to 400 nm. The visible light hand is comprised of wavelengths from about 400 to 780 nm. The near infrared band is comprised of wavelengths from about 0.78 to 1 μm. The short-wave infrared band is comprised of wavelengths from about 1 to 3 μm. The mid-wave infrared band is comprised of wavelengths from about 3 to 6 μm. The long-wave infrared band is comprised of wavelengths from about 6 to 14 μm. The far infrared band is comprised of wavelengths from about 14 to 40 μm. However, the boundary between near ultraviolet radiation and visible light along with the boundary between visible light and infrared radiation is not precisely defined, resulting in overlap between the bands.

The term electrically connected is defined to encompass an electrical current flow, including bidirectional, unidirectional, or any hybrid current flow, such as an uneven current.

FIG. **1** depicts a high level structural configuration for an energy harvesting system. FIG. **1**A illustrates a cross section of the structural configuration. FIG. **1**B shows an exploded three dimensional view. The interconnects and electrodes in the structural configurations depicted in FIGS. **1**A and B are not shown.

The energy harvesting system comprises a solar harvester **105**, a thermal harvester **110**, a battery **115**, and harvester electronics **120**. The thermal harvester **110** is located between the solar harvester **105** and the battery **115**. The harvester electronics **120** is attached to the thermal harvester **110** on the same side as the battery **115**. The solar harvester **105** and thermal harvester **110** are electrically isolated from each other and individually electrically connected to the harvester electronics **120**. The battery **115** is electrically connected to the harvester electronics **120**.

The solar harvester **105** and the thermal harvester **110** may be comprised of a photovoltaic or photoelectrochemical system. The solar harvester **105** may include any photovoltaic system which absorbs radiation within the near ultraviolet, visible, or near infrared bands to generate power. The solar harvester **105** may be comprised of any type of solar cell, including traditional crystallized silicon solar cells, thin film solar cells, multilayered solar cells, dye sensitized solar cells, or organic polymer solar cells. The material comprising the solar harvester may include, but is not limited to, amorphous silicon, polysilicon, crystalline silicon, Ge, SiGe, CdTe, ZnO, CdZnTe, HgCdTe, HgZnTe, GaAs, GaN, InP, GaSb, InSb, other semiconductors, light sensitive dyes, or polymers. A photovoltaic thermal harvester **105** may be comprised of a single junction or multiple junctions. The material comprising the thermal harvester **105** may include HgCdTe, HgZnTe, InSb, InAs, GaSb, GaAs, InP, PbTe, or polymers.

The battery **115** may be any type of rechargeable battery. One embodiment of the invention contemplates the use of solid state thin film battery may be comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, a single or multiple battery cells may be used. Optionally, in the case of multiple battery cells, the cells may be arranged in various configurations, e.g. series, parallel, etc. The battery **115** may be flexible, semi-flexible, or rigid. The battery **115** is electrically connected to the harvester electronics **120**.

The harvester electronics **120** may be comprised of circuitry which regulates the rate of charge and voltage level of the battery along with regulating the output of power to a load. In one embodiment of the invention, the harvester electronics may be comprised of a single chip integrated circuit. Optionally, the integrated circuits may be a CMOS circuit. Alternatively, an FPGA may be used for harvester electronics **120** to be configurable in the field. Optionally, the harvester electronics may be discretely integrated with the battery **115**. The harvester electronics may be flexible, semi-flexible, or rigid. The harvester electronics **120** may be powered by the battery **115**, energy from the solar harvester **105** or thermal harvester **110**, or a combination of energy sources.

The system is oriented to absorb radiation **100** arriving from the indicated direction, passing through the solar harvester **105** before reaching the thermal harvester **110**. The radiation **100** is comprised of the near ultraviolet, visible, near infrared, short-wave infrared, mid-wave infrared, long-wave infrared, and far infrared bands.

FIG. **2** illustrates the blackbody power as a function of wavelength at various temperatures. The blackbody radiation spectrum ranges from near ultraviolet to the infrared spectrum. Blackbody radiation has been largely overlooked as a potential energy source.

Blackbody radiation is a physical effect in which all objects at temperatures above 0 K emit electromagnetic power. The spectral radiance of an object is described through Planck's Law, which is presented as,

$$I(\lambda) = \frac{2hc^2}{\lambda^5\left(e^{\frac{hc}{\lambda kT}} - 1\right)},$$

where c is the speed of light, k is Boltzmann's constant, h is Planck's constant, λ is wavelength, and T is temperature in Kelvin of the object. By applying Lambert's cosine law to a hemispherical flux density from a flat surface, the maximum amount of incident radiation is equal to πI. This yields a maximum spectral radiance of

$$I(\lambda) = \frac{2\pi hc^2}{\lambda^5\left(e^{\frac{hc}{\lambda kT}} - 1\right)},$$

which best models the intensity of radiation from a planar source. As temperature increases, power (in watts per meters squared) increases at lower wavelengths. This results in the peak shifting towards lower wavelengths at higher temperatures.

As shown in FIG. **2**, at the temperatures ranging from −40° C. (233 K to +60° C., the peak power is at about 9 μm wavelength. Using Stefan-Boltzmann's law, $5.67\times10^{-8}\times T^4$, the total available blackbody radiation at a given temperature can be calculated. At room temperature, about 293 Kelvin, the total available blackbody radiation is estimated to be 413 W/m^2 with a peak between 7 to 10 μm.

FIG. **3** illustrates the discharge characteristics of a lithium-ion polymer cell at various currents. The figure shows that the cell maintains a relatively constant voltage, which drops sharply as the current decreases due to the battery's inherent resistance increasing. Given this characteristic of lithium-ion polymer cells, completely discharging cells, otherwise known as deep discharge, results in damage to the cells, which may include the inability to hold a charge and sustain a voltage across a load. To guard against this damage, low voltage protection is required. While the figure illustrates the characteristics for a 1.0 mAh grade lithium-ion polymer cell, the characteristics are similar for other lithium-ion polymer cells.

FIG. **4** illustrates a block diagram of the harvester electronics **120** utilizing a two circuit configuration. The harvester electronics **120** are comprised of a thermal harvester interface **400**, a solar harvester interface **405**, a battery manager **410**, and a voltage regulator **415**. Each component comprising the harvester electronics **120** may be electrically connected to and powered by the battery **115**. Optionally, the components of the harvester electronics **120** may be powered by the energy from the solar or thermal harvesters. Optionally, a combination of energy sources may be used to power the harvester electronics **120**. For example, the harvester electronics **120** may be powered by energy from the solar harvester **105** and the battery **115**.

The solar harvester **105** is electrically connected to the solar harvester interface **405**. The solar energy harvested by the solar harvester **105** is transferred to the solar harvester interface **405**. Optionally, the solar harvester interface may comprise a voltage boost to allow harvesting of solar energy at low voltages. Optionally, the voltage boost may be dynamically triggered below a certain threshold. The solar harvester interface is electrically connected to the battery manager **410**.

The thermal harvester **110** is electrically connected to the thermal harvester interface **400**. The thermal energy harvested by the thermal harvester **110** is transferred through the thermal harvester interface **400**. Due to the low voltage output of thermal energy, the thermal harvester interface **400** comprises a voltage boost. For example, the voltage boost may boost voltages from as low as 20 mV. The thermal harvester interface **400** is electrically connected to the battery manager **410**.

The solar harvester interface **405** and the thermal harvester interface **400** transfer the harvested energy to the battery manager **410**. The battery manager **410** merges the harvested energy from the solar harvester interface **405** and the thermal harvester interface **400**. This merged energy may be used to charge the battery **115** and/or be supplied to the electrically connected voltage regulator **415**. The battery manager **410** controls the rate of charge for the battery **115**. The rate of charge varies depending on the battery requirements. The battery manager **410** may be configured to disconnect the battery **115** from the output load when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. The voltage at which the battery manager **410** disconnects the battery varies depending on the battery specifications and configuration. For example, if the battery **115** is a lithium-ion polymer with discharge characteristics shown in FIG. **3**, the battery manager **410** will disconnect the battery from the load when the sharp voltage drop occurs. For example, but not to serve as a limitation, if the battery **115** is a 3.3 V lithium polymer battery, the battery manager **410** may be disconnect the battery from the load when the battery output voltage reaches 2.1 V. While the battery **115** is disconnected from the load, the battery manager **410** may continue to charge the battery **115** while providing power to the voltage regulator **415**.

Optionally, the battery manager **410** may include cell balancing capability when multiple battery cells are used. In the case where the battery cells have the same capacity, the battery manager **410** may differentially charge each cell to maximum capacity. In the case where the battery cells have varying capacities, the battery manager **410** may differentially charge each cell to maintain the same state of change.

The battery manager **410** may be configured to disconnect the battery **115** when the battery is fully charged to prevent overcharging. In the situation where the battery **115** is fully charged and disconnected from further charging, the battery manager **410** will direct all the harvested energy to the voltage regulator **415**. In the absence of adequate power from the solar harvester **105**, the battery manager **410** may utilize the battery **115** to supplement power from the thermal harvester **110** to the voltage regulator **415**.

The voltage regulator **415** maintains a constant voltage level output, which enables the harvester electronics **120** to produce a regulated power output **420**. The voltage regulator **415** may be comprised of a Low Drop Out (LDO) DC-DC voltage regulator. Optionally, other linear voltage regulators or switching regulators may be used. For example, but not to serve as a limitation, other linear voltage regulators may comprise zener regulators, series regulators, transistor regulators, or regulators comprising an op-amp. The voltage regulator **415** may be modular and configured to match a specific range of output loads or increase power output drive capability.

Optionally, the components of the harvesting electronics may be specifically configured to efficiently supply adequate power depending on the specific applications. While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **5** illustrates an alternate embodiment of the harvester electronics utilizing a two circuit configuration. The solar harvester **105**, thermal harvester **110**, battery **115**, thermal harvester interface **400**, solar harvester interface **405**, battery manager **410**, and voltage regulator **415** are as described above in FIG. **1** and FIG. **4**.

The harvester electronics comprises a bandgap reference **500**. The bandgap reference **500** is electrically connected to and powered by the battery **115**. Optionally, the bandgap reference may be powered separately by the battery manager, not shown. The bandgap reference **500** provides a temperature independent voltage reference (REF) **505**. The bandgap reference is electrically connected to the battery manager **410** and voltage regulator **415**, along with the MPPT controls and charge pump controls comprising the thermal harvester interface **400** and solar harvester interface **405** and outputs the REF **505** to each of the components.

The solar harvester interface **405** and thermal harvester interface **400** may he further comprised of individual maximum power point tracking (MPPT) inputs **510**, MPPT controls **515**, charge pumps **520**, and charge pump controls **525**. The different harvesting conditions for solar and thermal harvesters may result in different circuitry comprising the aforementioned components. The aforementioned components comprising the individual harvester interfaces may be powered by the battery **115**. Optionally, the components may be powered by the battery manager **410** or the solar or thermal harvester.

The MPPT input **510** is electrically connected to and receives input from the solar or thermal harvester and MPPT control **515**. The MPPT input **510** may track to match the input impedance to the maximum harvesting input impedance to achieve the greatest possible power harvest, during moment to moment variations of light level, shading, temperature, and photovoltaic module characteristics based on the input from the MPPT control **515**.

The MPPT control **515** is electrically connected to and receives input from the solar or thermal harvester and bandgap reference **500**. The input from the bandgap reference **500** comprises the REF **505**. The MPPT control **515** indicates to the MPPT input **510** whether the operating voltage of the harvesting input has changed in a given direction and to adjust the impedance accordingly. Optionally, the MPPT control **515** may determine the disturbance of the operating voltage of the harvesting input through a logic algorithm utilizing the REF **505** and harvester inputs. The MPPT input **510** is electrically connected to and provides an output to the battery manager **410**.

Optionally, the MPPT input **510** maybe electrically connected to the charge pump **520**. The charge pump **520** is electrically connected to and receives input, from the MPPT input **510** and the charge pump control **525**. The charge pump **520** may be comprised of a capacitive charge pump. Alternatively, the charge pump **520** may be comprised, of a step-up converter, boost converter, boost converter, another type of DC-DC converter, or a DC-AC converter coupled to a voltage multiplier. Optionally, the charge pump **520** may be comprised of multiple stages. For example, the charge pump **520** may pump from a voltage as low as 20 mV to over 4 V, using multiple stages to achieve the result.

The charge pump control **525** is electrically connected to and receives input from the bandgap reference **500** in the form of REF **505** Based on the REF **505**, the charge pump control **525** may adjust the oscillator frequency and the number of charge pump stages used by the charge pump **520**, which may be none, one, or multiple stages.

In an embodiment where the components of the harvester electronics **120** is powered by the battery **115**, the output from the MPPT input **510** to the battery manager **410** may serve as a bypass in the situation where the battery **115** goes below the harvester electronics **120** operating voltage. If the battery **115** goes below the harvester electronics **120** operating voltage, the components may fail to function. This bypass may allow the battery manager to recover the device with a voltage input that could drive the harvest electronics **120** and charge the battery **115** above the minimum operating voltage.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **6** illustrates a block diagram embodiment of the harvester electronics **120** in a single circuit configuration. The thermal harvester **110** is electrically connected to a voltage boost **600**. The voltage boost **600** may be comprised of a capacitive charge pump. Alternatively, the voltage boost **600** may be comprised of a step-up converter, boost converter, boost converter, another type of DC-DC converter, or a DC-AC converter coupled to a voltage multiplier. The voltage boost increases the low voltage input from the thermal harvester. The voltage boost **600** is electrically connected to the charge control **605**. The charge control **605** controls the energy storage for a first battery **610**. The boosted energy from the thermal harvester **110** is used to charge the first battery **610**. The charge control **605** controls the rate of charge and the battery voltage level of the first battery **610**. When the first battery **610** is fully charged, the charge control **605** disconnects the battery to prevent overcharging.

The first battery **610** may be comprised of any type of rechargeable battery. One embodiment of the invention contemplates the use of solid state thin film battery may be comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, the first battery **610** may be comprised of single or multiple battery cells.

The first battery **610** is electrically connected to the power management block **615**. The power management block disconnects the first battery **610** from the output load when the battery when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. For example, if the first battery **610** comprises a lithium-ion polymer battery with discharge characteristics similar to the depiction in FIG. **3**, the power management block **615** will disconnect the battery from the load when the sharp voltage drop occurs. Additionally, the power management **615** is electrically connected to a second battery **620**. The power management block **615** regulates the output voltage of the first battery **610** to charge the second battery **620**. Optionally, the charge control **605** and the power management block **615** may be combined into a single block to regulate the storage and output of the first battery **610**.

The second battery **620** may be comprised of any type of rechargeable battery. One embodiment of the invention contemplates the use of a solid state thin film battery comprised of lithium-ion polymer, lithium, semiconductor, polymer, or flexible batteries. Optionally, the solid state thin film battery may be discretely or monolithically integrated with the harvester. Optionally, in a separate embodiment, bulk batteries may be used. For example, rechargeable lithium air, nickel-cadmium, or nickel metal-hydride batteries. Optionally, the second battery **620** may be comprised of single or multiple battery cells. The second battery **620** is electrically connected to and receives solar energy input from the solar harvest regulator **625**.

The solar harvest regulator **625** is electrically connected to and receives input from the solar harvester **105**. Optionally, a zener protection diode may be used between the solar harvester **105** and solar harvest regulator **625** to protect the entire circuit. The solar harvest regulator **625** may comprise a mechanism to disconnect the second battery **620** once the battery reaches a full charge to prevent overcharging. Optionally, the solar harvest regulator **625** may be electrically connected to the voltage boost **600** and receives harvested thermal energy. Additionally, the solar harvest regulator **625** may comprise a voltage output regulator to disconnect the output when the battery discharge reaches a voltage threshold where further discharge would be harmful to the battery. Optionally, the solar harvest regulator may comprise a LDO regulator, another type of linear voltage regulator, or a switching regulator to control the output to a load. For example, but not to serve as a limitation, other linear voltage regulators may comprise zener regulators, series regulators, transistor regulators, or regulators comprising an op-amp. Optionally the solar harvest regulator **625** may protect the second battery **620** from unintended discharge when the input is lower than the battery voltage. For example, a zener protection diode may be used as a mechanism, where the voltage of the solar input must match the voltage of the battery plus the zener diode voltage.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or a combination of two or more blocks as discrete circuits.

FIG. **7** illustrates an alternate block diagram embodiment of the harvester electronics **120** in a single circuit configuration. The harvester electronics comprises a bandgap reference **700**. The bandgap reference **700** is electrically connected to and powered by the second battery **620**. Optionally, the bandgap reference may be powered separately by the solar harvest regulator **625**, not shown. The bandgap reference **700** provides a temperature independent voltage reference (REF) **705** output. The bandgap reference is electrically connected to the solar harvest regulator **625** and the MPPT control **715** for the thermal and solar harvester inputs and outputs the REF **505** to each of the components.

The MPPT input **710** is electrically connected to and receives input from the solar or thermal harvester and MPPT control **715**. The MPPT input **710** may track to match the input impedance to the maximum harvesting input impedance to achieve the greatest possible power harvest, during moment to moment variations of light level, shading, temperature, and photovoltaic module characteristics based on the input from the MPPT control **715**.

The MPPT control **715** is electrically connected to and receives input from the solar or thermal harvester and bandgap reference **700**. The input from the bandgap reference **700** comprises the REF **705**. The MPPT control **715** indicates to the MPPT input **710** whether the operating voltage of the harvesting input has changed in a given direction and to adjust the impedance accordingly. Optionally, the MPPT control **715** may determine the disturbance of the operating voltage of the harvesting input through a logic algorithm utilizing the REF **705** and harvester inputs.

Optionally, in another embodiment of the invention, a second bandgap reference, not shown, may be connected to the charge control **605** and the first battery **610**. The second bandgap reference is electrically connected to and provides a reference output to the MPPT control **715** connected to the thermal harvester **110**. This embodiment allows for individual MPPT tracking for different sources of harvested energy.

While the embodiment of the invention contemplates the harvester electronics **120** comprised on a single chip, alternate embodiments may comprise each block or at combination of two or more blocks as discrete circuits.

While the aforementioned embodiments depict harvesting, electronics which control the storage of energy and regulate output to a load for solar and thermal harvesters, the harvesting electronics may be configured to receive input from multiple sources of energy harvesting. Examples of other sources may include, but are not limited to air flow, temperature gradient, movement and transmitted radio frequencies.

Whereas many alterations and modifications of the present invention will no doubt become apparent to a person of ordinary skill in the art after having read the foregoing description, it is to be understood that the particular embodiments shown and described by way of illustration are in no way intended to be considered limiting. Therefore, reference to the details of the preferred embodiments is not intended to limit their scope.

The embodiments were chosen and described in order to explain the principles and applications of the invention, thereby allowing others skilled in the art to utilize the invention in its various embodiments and modifications according to the particular purpose contemplated. The scope of the invention is intended to be defined by the claims appended hereto and their equivalents.

The expected practical use of the present invention is the novel integrated perpetual energy harvester with energy storage and harvesting electronics. The proposed invention may be used as a one chip solution to store power from multiple sources of energy harvesting and regulate the output to a load.

What is claimed is:

1. A perpetual energy harvester comprising:

a photovoltaic thermal harvester wherein the photovoltaic thermal harvester generates the electrical energy from the blackbody radiation; and

a harvesting electronics in close proximity to the photovoltaic thermal harvester,

wherein the harvesting electronics receives input in the form of energy from the photovoltaic thermal harvester, and regulates the output to a load.

2. The perpetual energy harvester of claim **1**, further comprising a solar harvester, wherein said solar harvester is individually electrically connected to the harvesting electronics, and wherein said harvesting electronics further receives input in the form of energy from the solar harvester.

3. The perpetual energy harvester of claim **1**, further comprising a battery, wherein said battery is individually electrically connected to the harvesting electronics, and wherein said harvesting electronics further controls the amount of energy stored in said battery.

4. The perpetual energy harvester in claim **3**, wherein the said battery is selected from the group consisting of thin film lithium-ion, lithium-ion polymer, polymer, semiconductor, and flexible batteries.

5. The perpetual energy harvester in claim **2**, wherein the solar harvester is selected from the group consisting of traditional crystallized silicon solar cells, thin film solar cells, multi-layered solar cells, dye sensitized solar cells, and organic polymer solar cells.

6. The perpetual energy harvester in claim **1**,

wherein the photovoltaic thermal harvester is comprised of material selected from the group consisting of HgCATe, HgZnTe, InSb, InAs, GaSh, GaAs, InP, PbTe, and polymers, and wherein the harvesting electronics is comprised of a thermal harvester interface, and wherein the thermal harvester interface is electrically connected to and receives input from the thermal harvester.

7. A perpetual energy harvester comprising:

a photovoltaic thermal harvester wherein the photovoltaic thermal harvester generates the electrical enemy from the blackbody radiation;

a battery in close proximity to the photovoltaic thermal harvester; and

a harvesting electronics in close proximity to the photovoltaic thermal harvester and individually electrically connected to the photovoltaic thermal harvester, and to the battery, wherein the harvesting electronics receives input in the form of energy from the photovoltaic thermal harvester, controls the amount of energy stored in the battery, and regulates the output to a load.

8. The perpetual energy harvester of claim **7**, further comprising as solar harvester, wherein said solar harvester is individually electrically connected to the harvesting electronics, and wherein said harvesting electronics further receives input in the form of energy from the solar harvester.

9. The perpetual energy harvester in claim **7**, wherein the said battery is selected from the group consisting of thin film lithium-ion, lithium-ion polymer, polymer, semiconductor, and flexible batteries.

10. The perpetual energy harvester in claim **8**, wherein the solar harvester is selected from the group consisting of traditional crystallized silicon solar cells, thin film. solar cells, multi-layered solar cells, dye sensitized solar cells, and organic polymer solar cells.

11. The perpetual energy harvester in claim **7**, wherein the photovoltaic thermal harvester is comprised of material selected from the group consisting of HgCdTe, HgZnTe, InSb, InAs, GaSb, GaAs, InP, PbTe, and polymers, and wherein the harvesting electronics is comprised of a thermal harvester interface, and wherein the thermal harvester interface is electrically connected to and receives input from the thermal harvester.

12. A perpetual energy harvester comprising;

a solar harvester;

a photovoltaic thermal harvester in close proximity to the solar harvester, wherein the photovoltaic thermal harvester generates the electrical energy from the blackbody radiation;

and a harvesting electronics in close proximity to the photovoltaic thermal harvester and individually electrically connected to the solar harvester and to the photovoltaic thermal harvester, wherein the harvesting electronics receives input in the form of energy from the solar harvester and the photovoltaic thermal harvester, and regulates the output to a load.

13. The perpetual energy harvester of claim **12**, further comprising a battery, wherein said battery is individually electrically connected to the harvesting, electronics, and wherein said harvesting electronics further controls the amount of energy stored in said battery.

14. The perpetual energy harvester in claim **13**, wherein the said battery is selected from the group consisting of thin film lithium-ion, lithium-km polymer, polymer, semiconductor, and flexible batteries.

15. The perpetual energy harvester in claim **12**, wherein the solar harvester is selected from the group consisting of traditional crystallized silicon solar cells, thin film solar cells, multilayered solar cells, dye sensitized solar cells, and organic polymer solar cells.

16. The perpetual energy harvester in claim **12**, wherein the photovoltaic thermal harvester is comprised of material selected from the group consisting of HgCdTe, HgZnTe InSb, InAs, GaSb, GaAs, InP, PbTe, and polymers, and wherein the harvesting electronics is comprised of a thermal harvester interface wherein the thermal harvesting interface is electrically connected to and receives input from the thermal harvester, and also a solar harvester interface, wherein the solar harvester interface is electrically connected to and receives input from the solar harvester.

17. The perpetual energy harvester in claim **12**, wherein said harvesting electronics comprises:

a thermal harvester interface, wherein the thermal harvester interface is electrically connected to and receives input from the thermal harvester;

a solar harvester interface, wherein the solar harvester interface is electrically connected to and receives input from the solar harvester;

a battery manager electrically connected to and receives input from the solar harvester interface and thermal harvester interface, wherein the battery manager is electrically connected to the battery and manages the energy stored in the battery;

and a voltage regulator electrically connected to the battery manager, wherein the voltage regulator receives an input from the battery manager and controls an output voltage to an external load.

18. The perpetual energy harvester in claim **17**, wherein said voltage regulator further comprises a low drop out regulator.

19. The perpetual energy harvester in claim **17**, wherein said harvesting electronics further comprises a bandgap reference electrically connected to the thermal harvester interface, the solar harvester interface, the battery manager, and the voltage regulator, wherein the bandgap reference outputs a temperature independent voltage reference to the thermal harvester interface, the solar harvester interface, the battery manager, and the voltage regulator.

20. The perpetual energy harvester in claim **17**, wherein the solar harvester interface comprises:

a Maximum Power Point Tracking (MPPT) input electrically connected the solar harvester and the battery manager;

MPPT control electrically connected to the solar harvester, the MPPT input, and the bandgap reference, wherein the MPPT control receives a voltage reference input from the bandgap reference and an input from the solar harvester, determines if the operating voltage has changed, and outputs instructions to the MPPT input which adjusts input impedance to match maximum harvesting, input impedance;

a charge pump electrically connected to the MPPT input and the battery manager; and a charge pump control electrically connected to the charge pump and the bandgap reference, wherein the charge pump control receives input from the bandgap reference and dynamically adjusts oscillation frequency for the charge pump, and wherein the thermal harvester interface comprises;

a Maximum Power Point Tracking (MITT) input electrically connected to the thermal harvester and the battery manager;

a MPPT control electrically connected to the thermal harvester, the MPPT input, and the bandgap reference, wherein the MPPT control receives a voltage reference input from the bandgap reference and an input from the thermal harvester, determines if the operating voltage has changed, and outputs instructions to the MPPT input which adjusts input impedance to match maximum harvesting input impedance;

a charge pump electrically connected to the MPPT input and the battery manager;

and a charge pump control electrically connected to the charge pump and the bandgap reference, wherein the charge pump control receives input from the bandgap reference and dynamically adjusts oscillation frequency for the charge pump.

(57) **ABSTRACT**

A paraxial cloaking device provides a cloaking volume in which an item can be hid from view. A cloaking device includes an optical input receiving light rays and an optical output from which a continuous range of directions of the received light rays exit the paraxial cloaking device. The cloaking volume being disposed between the optical input and the optical output. For received light rays having incoming directions non-parallel to the reference optical axis up to a first angle, each of the received light rays exits the cloaking device substantially aligned with the respective received light ray and does not pass through the cloaking volume. The paraxial cloaking device has a unity magnification factor. In some instances, the paraxial cloaking device includes a phase matching element.

PARAXIAL CLOAK DESIGN AND DEVICE

CROSS-REFERENCE TO RELATED APPLICATIONS

This patent application claims priority to U.S. application Ser. No. 62/028,658 filed on Jul. 24, 2014 for a “Paraxial Cloak Design and Device,” the entire content of which is hereby incorporated by this reference.

STATEMENT AS TO RIGHTS TO INVENTIONS MADE UNDER FEDERALLY SPONSORED RESEARCH AND DEVELOPMENT

This work was supported by the Army Research Office Grant No. W911 NF-12-1-0263 and the DARPA DSO Grant No. W31P4Q-12-1-0015. The government has certain rights in the invention.

BACKGROUND

Optical spatial cloaking has captured the imagination of both the popular culture and scientific communities (see, e.g., Gbur, G. Invisibility physics: Past, present, and future. Progress in Optics 58, 65-114 (2013)). Seminal works in optical spatial cloaking includes work by Leonhardt (Leonhardt, U. Optical conformal mapping. Science 312, 1777-1780 (2006)) and Pendry, Schurig, and Smith (Pendry, J. B., Schurig, D. & Smith, D. R. Controlling electromagnetic fields. Science 312, 1780-1782 (2006)). These seminal works provide a theoretical framework to create a curved space for light waves, by carefully constructing materials in Cartesian space. This new field of research has been called ‘transformation optics’ (McCall, M. Transformation optics and cloaking Contemporary Physics 54, 273-286 (2013)). Experimental realization of such transformational optics has been difficult, due to the previously perceived need for artificial electric and magnetic materials (called ‘metamaterials’), the narrow-band spectrum involved, infinite phase velocity (or negative index to compensate this), and anisotropy in the theory (Gbur, G. Invisibility physics: Past, present, and future. Progress in Optics 58, 65-114 (2013)). Nonetheless, inspired by transformation optics, there have been some advances in optical spatial cloaking. These advances include a two-dimensional microwave cloak (Schurig, D. et al. Metamaterial electromagnetic cloak at microwave frequencies. Science 314, 977-980 (2006)); a ‘carpet cloak’ that hides an object under a surface (Li, J. S. & Pendry, J. B. Hiding under the carpet: A new strategy for cloaking Physical Review Letters 101, 203901 (2008)); and even cloaking in time (Fridman, M., Farsi, A., Okawachi, Y. & Gaeta, A. L. Demonstration of temporal cloaking Nature 481, 62-65 (2012)), and (Lukens, J. M., Leaird, D. E. & Weiner, A. M. A temporal cloak at telecommunication data rate. Nature 498, 205-208 (2013)). A few groups have been able to cloak millimeter- to centimeter-sized objects as well, using birefringent materials (Zhang, B. L., Luo, Y. A., Liu, X. G. & Barbastathis, G. Macroscopic invisibility cloak for visible light. Physical Review Letters 106, 033901 (2011)), and (Chen, X. Z. et al. Macroscopic invisibility cloaking of visible light. Nature Communications 2, 176 (2011)).

To overcome the metamaterial requirements (in some implementations) and to extend cloaking to a broadband, visible regime for large objects, researchers have recently looked to ray optics for cloaking (see, e.g., Chen, H. et al. Ray-optics cloaking devices for large objects in incoherent natural light. Nature Communications 4, 2652 (2013); Zhai, T. R., Ren, X. B., Zhao, R. K., Zhou, J. & Liu, D. H. An effective broadband optical ‘cloak’ without metamaterials. Laser Physics Letters 10, 066002 (2013); and Howell, J. C., Howell, J. B. & Choi, J. S. Amplitude-only, passive, broadband, optical spatial cloaking of very large objects. Applied Optics 53, 1958-1963 (2014)). In these cloaks, the amplitude and direction of light fields are considered, as opposed to the full preservation of fields (amplitude and phase) of transformation optics. These designs have been able to cloak centimeter to meter-sized objects with commonly available optics. Yet, these schemes work only for unidirectional incident light, as they are not designed for continuous multidirectional cloaking, and can have non-unity magnifications. For off-axis, non-zero angles, the background images show distortion and positional shifts. This is particularly true if the background is far away from the cloaking device. In addition, as seen in FIG. 1 of Howell, J. C., Howell, J. B. & Choi, J. S. Amplitude-only, passive, broadband, optical spatial cloaking of very large objects. Applied Optics 53, 1958-1963 (2014), rays that propagate through the system, but go through the center at non-zero angles, can actually enter the cloaking region, effectively uncloaking the space.

Despite the advances in cloaking, a 3-D multidirectional cloak has been elusive. As shown by Wolf and Habashy (Wolf, E. & Habashy, T. Invisible bodies and uniqueness of the inverse scattering problem. Journal of Modern Optics 40, 785-792 (1993)) and Nachman (Nachman, A. I. Reconstructions from boundary measurements Annals of Mathematics 128, 531-576 (1988)), no isotropic cloaking scheme can hide an object from all viewing angles. Their work answered a question that stemmed from Devaney (Devaney, A. J. Nonuniqueness in inverse scattering problem. Journal of Mathematical Physics 19, 1526-1531 (1978)), who elegantly showed how to mathematically construct potentials that have zero scattering fields, and are hence invisible. Devaney’s result, however, was for a finite number of discrete directions, and not for a continuous range of angles.

BRIEF SUMMARY

The following presents a simplified summary of some non-limiting embodiments of the invention in order to provide a basic understanding of the invention. This summary is not an extensive overview of the invention. It is not intended to identify key/critical elements of the invention or to delineate the scope of the invention. Its sole purpose is to present some embodiments of the invention in a simplified form as a prelude to the more detailed description that is presented later.

Paraxial cloaking devices and related methods, as described herein, provide a cloaking volume by which an object can be hidden from view relative to a continuous range of viewing directions. The cloaking devices described herein can be constructed with readily available off-the-shelf isotropic optical components, such as lenses and mirrors, thereby negating the need for any artificial electric and/or magnetic materials (i.e., metamaterials) in at least some implementations. Such devices have potential usages in many different fields, for example, in secure communications, transportation, military applications, and medical devices.

In one non-limiting embodiment, a paraxial cloaking device having a cloaking volume and a reference optical axis is provided. The cloaking device includes an optical input receiving incoming light rays and an optical output from which a plurality of the light rays exit the paraxial cloaking device. The optical output is offset along the optical axis from the optical input. The cloaking volume is disposed between the optical input and the optical output. For light rays having incoming directions that are non-parallel to the reference optical axis up to a first angle between the incoming light ray and the reference optical axis, each of the light rays exits the cloaking device substantially aligned with the respective incoming light ray and does not pass through the cloaking volume. The paraxial cloaking device has a unity magnification factor (i.e., the cloaking device does not affect the apparent size of the objects in the image to the viewer).

In some instances, a paraxial cloaking device hides the cloaking volume for viewing directions that are significantly off-axis. For example, in some instances, the first angle is up to 3.5 degrees, up to 5 degrees, or even up to 15 degrees or more.

In some instances, a paraxial cloaking device imparts an optical transformation to the received light rays defined by an ABCD matrix, wherein A=1, B=L/n, C=0, and D=1; L being a length between the optical input and the optical output, and n being an index of refraction for the surrounding/ambient medium, before and/or after, the cloaking device.

Various configurations of a paraxial cloaking devices are possible. For example, in some instances a paraxial cloaking device includes a first lens, a first mirror, a second mirror, a third mirror, and a second lens. The first and second lenses are centered on the reference optical axis. The first and third mirrors are tilted relative to the reference optical axis. The second mirror is curved. The optical input includes the first lens. The optical output includes the second lens. A light ray passing through the cloaking device follows an optical propagation path. The second mirror is disposed along the optical propagation path between the first and second lenses. The first mirror is disposed along the optical propagation path between the first lens and the second mirror. And the third mirror is disposed along the optical propagation path between the second mirror and the second lens. The first and second lenses can have the same focal length. The first lens and the first mirror can be separated by a distance equal to a distance separating third mirror and the second lens. And the first mirror and the second mirror can be separated a distance equal to a distance separating the second mirror and the third mirror.

As another example, in some instances a paraxial cloaking device includes a first lens, a first mirror, a second lens, a second mirror, a third lens, a third mirror, and a fourth lens. The first and fourth lenses are centered on the reference optical axis. The first and third mirrors are tilted relative to the reference optical axis. The optical input includes the first lens. The optical output includes the fourth lens. A light ray passing through the cloaking device follows an optical propagation path. The second mirror is disposed along the optical propagation path between the first and fourth lenses. The first mirror is disposed along the optical propagation path between the first lens and the second mirror. The third mirror is disposed along the optical propagation path between the second mirror and the fourth lens. The second lens is disposed along the optical path between the first and second mirror. And the third lens is disposed along the optical path between the second and third mirrors. The first and fourth lenses can have the same focal length. The first lens and the first mirror can be separated by a distance equal to a distance separating third mirror and the fourth lens. The first mirror and the second lens can be separated a distance equal to a distance separating the third lens and the third mirror. The second and third lenses can have the same focal length. And the second lens and the second mirror can be separated a distance equal to a distance separating the second mirror and the third lens.

As another example, a paraxial cloaking device can be rotationally symmetric and includes three or more lenses. For example, a rotationally symmetric cloaking device can include three or more lenses that are centered on the reference optical axis. As another example, a rotationally symmetric cloaking device can include four or more lenses that are centered on the reference optical axis. At least one of the lenses can include an achromatic doublet to reduce aberrations.

In another non-limiting embodiment, a related method of designing a cloaking device is disclosed. The method includes selecting and positioning optical components of a candidate cloaking device and calculating an ABCD matrix for the candidate cloaking device. The optical components are selected and positioned such that A=1, B=L/n, C=0, and D=1; L being a length between the optical input and the optical output, n being an index of refraction for the surrounding/ambient medium, before and/or after, the cloaking device. In some instances, the method further includes adjusting at least one of a parameter or a position of at least one of the optical components of the candidate cloaking device so as to compensate for a thickness of at least one of the optical components of the candidate cloaking device. In some instances, the method further includes tracing at least one ray through the candidate cloaking device to assess a deviation between the location and direction of the ray prior to being received by the candidate cloaking device and after exiting the candidate cloaking device, and adjusting at least one of a parameter and a position of at least one of the optical components of the candidate cloaking device based on the deviation assessment so as to reduce the deviation.

In another non-limiting embodiment, a method for designing a cloaking device having a desired cloaking volume is disclosed. Such a method can include selecting any suitable cloaking device as described herein to be scaled to provide the desired cloaking volume. A scale factor indicative of a size difference between the desired cloaking volume and the cloaking volume of the selected cloaking device is determined. Configuration parameters of the second cloaking device are determined by scaling corresponding configuration parameters of the selected cloaking device by the scale factor.

In some instances, the paraxial cloaking devices described herein can be constructed from readily available existing optical components, for example, lenses and mirrors. In some instances, a paraxial cloaking device does not include a metamaterial (e.g., artificial electric and/or magnetic material) optical component. And in some instances, a paraxial cloaking device does not include a non-isotropic optical component. In other instances, a paraxial cloaking device does include a metamaterial.

In some instances, the cloaking device includes a metamaterial optical component.

In some instances, the cloaking device further includes a phase matching element. The phase matching element may be in some instances a flat plate having at least one index of refraction and a longitudinal length. The phase matching element may be in some instances an anomalous dispersion element. The phase matching element may be or include a metamaterial in some instances. The phase matching element may have a negative index of refraction in some instances.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. **1**A and **1**B are simplified diagrammatic illustrations of an 'identity' optical transformation.

FIG. **1**C is a simplified diagrammatic illustration of an optical transformation of a paraxial cloaking device, in accordance with some instances.

FIG. **2** is a simplified diagrammatic illustration of an optical transformation.

FIG. **3** is a simplified diagrammatic illustration of a paraxial cloaking device, in accordance with some instances.

FIG. **4** illustrates a ray tracing assessment performed on a cloaking device in accordance with the cloaking device of FIG. **3**.

FIG. **5** illustrates a ray tracing assessment performed on an optimized cloaking device in accordance with the cloaking device of FIG. **3**.

FIG. **6** is a simplified diagrammatic illustration of a paraxial cloaking device having a rotationally symmetric improvement, in accordance with some instances.

FIG. **7** illustrates a ray tracing assessment performed on a cloaking device in accordance with the cloaking device of FIG. **6**.

FIG. **8** illustrates a ray tracing assessment performed on a scaled version of the cloaking device of FIG. **7**.

FIG. **9** is a simplified diagrammatic illustration of a two lens device.

FIG. **10** is a simplified diagrammatic illustration of a rotationally-symmetric three lens paraxial cloaking device, in accordance with some instances.

FIG. **11** is a simplified diagrammatic illustration of a rotationally-symmetric four lens paraxial cloaking device, in accordance with some instances.

FIG. **12** shows a plot of parameters for possible four lens, rotationally-symmetric, paraxial cloaking devices, in accordance with some instances.

FIG. **13**A and FIG. **13**B illustrate a ray tracing assessment performed on an example three lens paraxial cloaking device.

FIG. **14** illustrates a cloaked region for the example three lens paraxial cloaking device of FIG. **13**.

FIG. **15** shows an image taken from an on-axis viewpoint looking through a prototype three lens paraxial cloaking device, in accordance with some instances.

FIG. **16** shows an image taken from an off-axis (0.55 degrees) viewpoint looking through the prototype three lens paraxial cloaking device of FIG. **15**.

FIG. **17** shows an image taken from an off-axis (0.83 degrees) viewpoint looking through the prototype three lens paraxial cloaking device of FIG. **15**.

FIG. **18** shows an image taken from an off-axis (1.11 degrees) view point looking through the prototype three lens paraxial cloaking device of FIG. **15**.

FIG. **19** shows a side profile image of three lens paraxial cloak of FIG. **15**.

FIG. **20** illustrates a ray tracing assessment performed on an example four lens paraxial cloaking device.

FIG. **21** shows ray tracing simulation results on a four lens paraxial cloak that has been scaled up to twice the size of the four lens paraxial cloak of FIG. **20**.

FIG. **22** shows a side profile image of a prototype four lens paraxial cloak.

FIG. **23** shows an image taken from an off-axis (−0.65 degrees) viewpoint looking through the prototype four lens paraxial cloaking device of FIG. **22**.

FIG. **24** shows an image taken from an on-axis (0.0 degrees) viewpoint looking through the prototype four lens paraxial cloaking device of FIG. **22**.

FIG. **25** shows an image taken from an off-axis (0.47 degrees) viewpoint looking through the prototype four lens paraxial cloaking device of FIG. **22**.

FIG. **26** shows an image taken from an off-axis (0.95 degrees) viewpoint looking through the prototype four lens paraxial cloaking device of FIG. **22**.

FIG. **27** illustrates a ray tracing assessment performed on an example split three lens paraxial cloaking device.

FIG. **28** illustrates a ray tracing assessment performed on an example combined four lens paraxial cloaking device.

FIG. **29** is a simplified diagram of a three-dimensional adaptation of the two-dimensional cloak shown in FIG. **3**.

FIG. **30** is a simplified diagram of a three-dimensional adaptation of the two-dimensional cloak shown in FIG. **6**.

FIG. **31** shows possible applications of cloaking devices.

FIG. **32** is a simplified diagrammatic illustration of a paraxial cloaking device, in accordance with some instances.

FIG. **33** is a chart of various thin, flat plates that may be used to match a full-field cloak condition in some instances.

DETAILED DESCRIPTION

In the following description, some non-limiting embodiments of the present invention will be described. For purposes of explanation, specific configurations and details are set forth in order to provide a thorough understanding of the embodiments. It will, however, also be apparent to one skilled in the art that the present invention may be practiced without the specific details. Furthermore, well-known features may be omitted or simplified in order not to obscure the embodiment being described.

In some instances, the paraxial cloaking devices disclosed herein require no new materials (e.g., artificial electric and/or magnetic materials—"metamaterials"), use isotropic off-the-shelf optics, scale easily to cloak relatively large objects, and are as broadband as the choice of optical material, all of which have been challenges for previous cloaking schemes. In addition, a concise formalism is provided that quantifies and produces optical cloaks that can be used to cloak an object with respect to a small-angle ('paraxial') limit. To a first approximation, the paraxial cloaking devices disclosed herein accurately replicate the ambient space.

Characterizing a Paraxial Optical Spatial Cloak

Referring now to the drawings, in which like reference numerals represent like parts throughout the several views, FIGS. **1**A through **1**C schematically illustrate possible candidate for ray-based optical spatial cloaking FIG. **1**A illustrates an identity transformation, in which rays entering an identity transformation black box **10** from the left and exit to the right with the same positions and directions. FIG. **1**B illustrates how an observer **12** would view an object **14** disposed behind the identity transformation black box **10**. To the observer **12**, the object **14** would appear to be closer than its actual position, by the length of the box, and therefore appear to be located at image **16**. Although the identity transformation is a good candidate for ray-based optical spatial cloaking, an ideal cloaking device would make objects behind the cloaking device appear to be exactly where they are. In other words, an ideal cloaking device should act the same way as if it was filled with the surrounding medium. For example, to cloak in air, the cloaking device should act as it was filled with air. FIG. **1**C schematically illustrates an example 'ideal' cloaking device **20**.

We can then define an ‘ideal cloak’ for ray optics—it contains a non-zero volume to hide an object, and it behaves as if its entire space was replaced by the surrounding medium, for all light rays entering it.

ABCD Matrix

The characteristics of the cloaking devices described herein can be quantified and defined with the aid of linear equations. Referring now to FIG. **2**, to a first approximation, also referred to herein as the “paraxial approximation,” light rays are assumed to deviate minimally from the axis of rotational symmetry for the system (z in FIG. **2**). In the paraxial approximation, as indicated in equation (1) below, ray angles are assumed to be small. Each light ray can be described by its position y and the paraxial angle u, much like an object is described by position and momentum.

$$u \equiv \tan\theta \approx \theta, \tag{1}$$

For the above case, it is assumed that the system is rotationally symmetric about the z-axis. Theta (θ) in equation (1) is the angle of the light ray from the z-axis.

Because of the linearity of optics in the paraxial approximation, the propagation of light rays through an optical system can be described by matrices. These matrices are referred to herein as ‘ray transfer’ matrices, or ‘ABCD’ matrices. Equation (2) below shows how an ABCD matrix is used.

$$\begin{bmatrix} y' \\ n'u' \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} y \\ nu \end{bmatrix}, \tag{2}$$

In equation (2), n and n' are the indices of refraction for the space before and after the optical system, respectively (See FIG. **2**, where rays travel from left to right). The ABCD matrix defines the transformation accomplished on the light rays by the optical system (e.g., optical system **22** schematically represented in FIG. **2**). The ABCD matrix maps the initial position (y) and angle (u) of incoming light rays to corresponding light rays exiting the system (y', u'). The space before the optical system (represented mathematically by the ABCD matrix) is referred to herein as the “object space” with index of refraction n. In a similar fashion, the space after the optical system is referred to herein as the “image space” with index of refraction n'. In FIG. **2**, y>0, u>0, y'<0, and u'<0, with the sign convention used. The ABCD matrix for a space of length t, with index of refraction n_t, is shown in equation (3) below.

$$M_t = \begin{bmatrix} 1 & t/n_t \\ 0 & 1 \end{bmatrix}. \tag{3}$$

In some instances of a paraxial cloaking device, the ABCD matrix is as set forth in equation (3) above, where t=L is the length of the optical system, and n_t=n=n'. This is because a paraxial cloaking device should replicate the surrounding medium throughout its volume. Substituting into equation (3) yields equation (4).

$$\begin{bmatrix} y' \\ nu' \end{bmatrix} = \begin{bmatrix} 1 & L/n \\ 0 & 1 \end{bmatrix} \begin{bmatrix} y \\ nu \end{bmatrix} = \begin{bmatrix} y + Lu \\ nu \end{bmatrix} \tag{4}$$

In equation (4), the angle of the exiting light ray is set equal to the angle of the incoming light ray and the position y of the light ray shifts by the angle multiplied by the length (i.e., y'=y+Lu). Equation (4) sets forth the optical transformation for a paraxial optical cloaking system that applies to all light rays that would be seen by an observer, at least within the accuracy associated with the first order of approximation set forth above. Equation (4) is compatible with the findings of Wolf and Habashy (E. Wolf and T. Habashy, Journal of Modern Optics 40, 785 (1993)) and Nachman (A. I. Nachman, Annals of Mathematics 128, 531 (1988)) since Equation (4) is based on the paraxial approximation described above, and hence not applicable at large angles. Equation (4), however, has been shown to set forth an effective condition, despite its conciseness. For clarity, the ABCD matrix of equation (4) is restated below in equation (5).

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}_{ideal\ cloak} = \begin{bmatrix} 1 & L/n \\ 0 & 1 \end{bmatrix}, \tag{5}$$

In equation (5), L and n are the length of the cloaking system and index of refraction of the surrounding medium, respectively. Because ABCD matrices have a determinant of 1, equation (5) gives only three conditions to be satisfied:

$$B=L/n, C=0, \text{ and } (A=1 \text{ or } D=1). \tag{6}$$

Note that the cloaking system per equation (4) is “afocal” (C=0). Afocal optical systems have no net focusing power, so, for example, an object at infinity will be imaged to infinity. This aspect is helpful when designing a cloaking system satisfying equation (4), since an afocal condition can be easily checked.

Example Paraxial Optical Spatial Cloaks

FIG. **3** illustrates a first example of a paraxial cloak **30**, in accordance with some instances. The paraxial cloak **30** contains a non-zero volume to hide an object, and satisfies equation (5) with corrected signs to include the mirrors (See equation (8)). While only the on-axis ray is shown (thick arrows), the paraxial cloak **30** also works for off-axis rays from other possible ray directions and positions, at least with respect to off-axis directions within the small angle assumption used to formulate equation (5).

The paraxial cloak **30** works for two-dimensions. To make it work for off-axis angles in three-dimensions, the device can be manufactured by rotating the two-dimensional design by a full 180 degrees about the dotted line that connects the centers of lenses **1** and **5** in FIG. **3** (So each layer should replicate this two-dimensional design throughout the 180 degrees; mirrors **2** and **4** will be shaped similar to bowties (two half-cones attached), mirror **3** will be shaped as a toroidal shell, and the lenses will remain spherical). This is shown in FIG. **29**.

For simplicity, the paraxial cloak **30** is in air, with the index of refraction of air (n_{air}) set to 1. The ABCD Matrix for the paraxial cloak **30** is given in equation (7).

$$\begin{bmatrix} 1 & 0 \\ 1/f_5 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & -t_4 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & t_3 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ \frac{-2}{r_3} & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & -t_2 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & t_1 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ -1/f_1 & 1 \end{bmatrix}, \tag{7}$$

In equation (7), the t's are the longitudinal distances (along the bent z-axis) between each optical element, the f's are the focal lengths, and r_3 is the radius of curvature of the center mirror (See FIG. **3**). The four thick arrows in FIG. **3** follow the path of an on-axis ray. Note that equation (7) is based on a thin lens approximation. Also, the z-axis follows the thick arrows, since this is the center axis of symmetry.

Care must be given to use the correct signs for each of the terms in equation (7), so as to remain consistent. Otherwise, the correct solution space will not be found. One sign convention that can be used is set forth in D. Buralli, OPT 441—Geometrical Optics (The Institute of Optics, University of Rochester, Rochester, N.Y., U.S.A., 2010), where after odd number of reflections the propagation distance t and the index of refraction n change signs. With this convention, the space in which light exits (to the far-right) has index of refraction $n_5=-n_{air}=-1$ and the y-axis also changes signs (by carefully considering propagation directions). Incorporating this sign convention into equation (4) for the paraxial cloak **30** yields equation (8).

$$\begin{bmatrix} y' \\ -u' \end{bmatrix} = \begin{bmatrix} -1 & -L \\ 0 & -1 \end{bmatrix} \begin{bmatrix} y \\ u \end{bmatrix} = \begin{bmatrix} -(y+Lu) \\ -u \end{bmatrix}. \tag{8}$$

In some instances, a paraxial cloak is configured to undo any changes that the first half of the paraxial cloak makes on the light rays. By doing so, the rays may retain the same direction, similar to a retro-reflector. This can be done by making the second half of the paraxial cloak **30** symmetric to the first half (i.e., $f_5=-f_1$, $t_4=-t_1$, $t_3=-t_2$). As a result, f_1 can be solved for as shown in equation (9) such that A=−1 for the ABCD matrix.

$$f_1=t_1-t_2. \tag{9}$$

Serendipitously, this is the same condition that sets C=0. As noted above, D=−1 is automatically satisfied. Equation (9) shows that requiring a paraxial cloak to have symmetric halves is helpful in some instances.

With f_1 set to equation (9), the ABCD matrix for a paraxial cloak simplifies to:

$$\begin{bmatrix} -1 & 2(t_1-t_2)(r_3-t_1+t_2)/r_3 \\ 0 & -1 \end{bmatrix}. \tag{10}$$

The radius of curvature of the center mirror, r3, can then be determined so as to satisfy the remaining condition: B=−L. Using the geometry of the paraxial cloak **30** shown in FIG. **3** yields an overall device length per equation (11).

$$L=2(t_1-t_2\sin(2\alpha-3\pi/2)). \tag{11}$$

Solving for r3 yields:

$$r_3=-\frac{(t_1-t_2)^2}{-2t_1+t_2+t_2\cos(2\alpha)}. \tag{12}$$

Notably, if $r_3=f_1$, then B=0. It can be seen that such an optical system can either be an identity transformation or a cloaking system.

Only equations (9) and (12) need to be met for the optical system **30** to be an ideal paraxial cloak. For example, with a lens with $f_1=200$ mm, mirror **2** tilt angle $\alpha=150$ degrees, and $t_2=-40$ mm, t_1 and r_3 can be solved for yielding $t_1=160$ mm and $r_3=105.3$ mm. The net length of the system **30** is L=360 mm.

Using these values, light rays within and beyond the small angle paraxial approximation were traced using CODE V, which uses Snell's Law directly and accurately simulates light rays in actual lenses. FIG. **4** shows the simulation results. For the simulation, t_1 was obtained by subtracting $|t_2|$ from the back focal length of the lens used, to properly account for the lens thickness (so $t_1\approx150$ mm). The simulation showed that incoming on-axis rays **32**-*i***1**, **32**-*i***2**, **32**-*i***3** are un-deviated relative to their respective outgoing rays **32**-*o***1**, **32**-*o***2**, **32**-*o***3**, and that incoming off-axis rays **34**-*i***1**, **34**-*i***2**, **34**-*i***3**, **36**-*i***1**, **36**-*i***2**, **36**-*i***3** are only slightly shifted relative to their respective outgoing rays **34**-*o***1**, **34**-*o***2**, **34**-*o***3**, **36**-*o***1**, **36**-*o***2**, **36**-*o***3** while maintaining their initial angles quite closely.

CODE V was used to optimize the paraxial cloak to bring the center of the angled rays closer to where they should be located. Specifically, only the curvature of the center mirror (r_3) was optimized to obtain the improvement shown in FIG. **5**. Although the size of the ray bundles entering the system ("entrance pupil") was the same, the required minimum diameter of the last lens was reduced by over 20 mm. The range of incident angles that the resulting optical cloak can accept ("field-of-view") was −3.5 degrees to +3.5 degrees.

The results in each of FIG. **4** and FIG. **5** show some shifts in the positions of the off-axis rays. It is easy to conclude that this result may be due to the use of the small angle paraxial approximation. A close examination shows that the transverse shifts are different for different incident angles. This suggests that the paraxial cloak is not rotationally symmetric. This may be because the center mirror has a non-zero focusing power and a tilt, simultaneously.

Rotationally Symmetric Improvement

Typically, the ABCD ray tracing matrices assume rotational symmetry since only y is used, instead of both x and y. The paraxial cloak **30** of FIG. **3**, however, is not rotationally symmetric. The rotational symmetry of the paraxial cloak **30** can be improved. For example, the center mirror **3** can be replaced with focusing lenses **2'**, **3'** and a flat mirror **3"** to result in a paraxial cloak **40** illustrated in FIG. **6**. The ABCD matrix for the resulting paraxial cloak **40** is given by equation (13).

$$\begin{bmatrix} 1 & 0 \\ 1/f_5 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & -t_4 \\ 0 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & t_3' \\ 0 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & 0 \\ -1/f_3' & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & t_3 \\ 0 & 1 \end{bmatrix}\cdot \begin{bmatrix} 1 & -t_2' \\ 0 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & 0 \\ 1/f_2' & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & -t_2 \\ 0 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & t_1 \\ 0 & 1 \end{bmatrix}\cdot\begin{bmatrix} 1 & 0 \\ -1/f_1 & 1 \end{bmatrix} \tag{13}$$

In addition to replacing the center mirror, a selected focal length f_1 is for lens **1** is used and a corresponding solution for t1 is found. This was done because it is usually easier to purchase a ready-made lens and then adjust the spacing, rather than the other way around. Setting A=−1 and C=0 yields equation (14) for t_1.

$$t_1=[f_1(f_2'-t_2')+f_2'(t_2+t_2')-t_2t_2']/(f_2'-t_2'). \tag{14}$$

With t1 set to equation (14), the ABCD matrix for the paraxial cloak **40** is given by equation (15).

$$\begin{bmatrix} -1 & (2f_1[f_2'^2+f_1(f_2'-t_2')])/f_2'^2 \\ 0 & -1 \end{bmatrix}. \tag{15}$$

Similar as for the paraxial cloak **30** of FIG. **3**, the focal length of lens **2'** can be solved. B is set equal to −L' where the total length L' is given by equation (16).

$$L'=2(t_1-(t_2+t_2')\sin(2\alpha-3\pi/2)). \tag{16}$$

Solving for the focal length of the second lens **2'** yields equation (17).

$$f_2' = -\frac{f_1^2 \pm \sqrt{f_1^2(f_1^2+4f_1t_2'+2t_2'L')}}{2f_1+L'}. \tag{17}$$

Only equations (14) and (17) need to be satisfied for the paraxial cloak **40**. Equations (14) and (17), however, form transcendental equations because L' is a function of t_1 (equation (16)). At this point, t1 and the focal length of the second lens **2'** can be solved for numerically.

It is important to note that the equations above assume that all the lenses are infinitely thin. In reality, lenses have thicknesses, and this can make a large difference in obtaining the correct solutions for equation (5). Hence, further steps can be taken to correct equations (14) and (17) for the use of 'thick' lenses.

As an example, a simulation was run for the paraxial cloak **40**. The simulation was run using CODE V to accomplish ray tracing. The result is shown in FIG. **7**. The field-of-view was the same as for the paraxial cloak **30** of FIG. **3** (−3.5 to +3:5 degrees), but the entrance pupil was increased to 40 mm. Increasing the entrance pupil allows more light to enter, which improves the resolution and 'speed' of the optical system. Even without any separate CODE V optimization, a large improvement is seen over the paraxial cloak **30** simulation results shown in FIG. **4**. The rays are closer to where they need to be, and the size of the rays exiting the system has not increased much even compared to optimized paraxial cloak simulation results shown in FIG. **5**.

The paraxial cloak **40** (or any other paraxial cloak described herein) can be scaled to any suitable size by scaling all radii of curvature, lengths, and entrance pupil by the same factor. For example, the simulation results shown in FIG. **8** are for a doubling of the size of the paraxial cloak **40**, which results in a doubling of the corresponding cloaking space.

The paraxial cloak **40** works for multiple off-axis rays in two-dimensions. For three-dimensions, the device can be manufactured with each layer replicating this two-dimensional design throughout a full 180 degrees, rotating about the dotted line connecting the centers of lenses **1** and **5**, as seen in FIG. **6**. Mirrors **2** and **4** will be shaped similar to bowties (two half-cones attached), mirror **3** will be shaped as a half-pipe, lenses **1** and **5** will remain spherical, and lenses **2'** and **3'** will be clipped, half-cone shapes with varying thicknesses across. This is shown in FIG. **30**.

Rotationally Symmetric Paraxial Cloaks with Lenses

Rotationally symmetric paraxial cloaks are described herein that utilize three thin lenses and four thin lenses, respectively. We will assume the cloaks are in air, for these cases. The ABCD matrix for one thin lens is given by equation (18), where f is the focal length of the lens.

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}_{thin\ lens} = \begin{bmatrix} 1 & 0 \\ -1/f & 1 \end{bmatrix}, \tag{18}$$

It can be seen that equation (18) will satisfy equation (5) only if f=+/−infinity, i.e., the lens has no optical power (e.g., a flat lens). Such a lens, however, provides no cloaking region and no optical effect.

Instead, attention is now turned to multiple lens systems. In the following derivations, f's are used to denote the focal lengths, and t's are used to denote the distances between the optical elements. Starting with a two lens system as shown in FIG. **9**, the ABCD matrix is given by equation (19).

$$\begin{bmatrix} 1 & 0 \\ -1/f_2 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ -1/f_1 & 1 \end{bmatrix} = \begin{bmatrix} 1-t/f_1 & t \\ -(f_1+f_2-t)/(f_1f_2) & 1-t/f2 \end{bmatrix}. \tag{19}$$

Similar to the one lens system, it can be seen that equation (19) will satisfy equation (5) only if $f_1=f_2=$+/−infinity. This is a system that is essentially made of air only, quite literally, again with no cloaking region nor optical effect.

Turning now to a three lens system as shown in FIG. **10**, the ABCD matrix is given by equation (20).

$$\begin{bmatrix} 1 & 0 \\ -1/f_3 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & t_2 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ -1/f_2 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & t_1 \\ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ -1/f_1 & 1 \end{bmatrix}. \tag{20}$$

Setting C=0 and solving for f_2 yields equation (21).

$$f_2 = -\frac{(f_1-t_1)(f_3-t_2)}{f_1+f_3-t_1-t_2}. \tag{21}$$

Using equation (21), the ABCD matrix is given by equation (22).

$$\begin{bmatrix} \frac{f_3(f_1-t_1)}{f_1(f_3-t_2)} & t_1+t_2+t_1t_2\frac{(f_1+f_3-t_1-t_2)}{(f_1-t_1)(f_3-t_2)} \\ 0 & \frac{f_1(f_3-t_2)}{f_2(f_1-t_1)} \end{bmatrix}. \tag{22}$$

Setting B=t1+t2 yields equation (23).

$$t_1t_2\frac{(f_1+f_3-t_1-t_2)}{(f_1-t_1)(f_3-t_2)} = 0. \tag{23}$$

Equation (23), however, is only true if $t_1=0$, or $t_2=0$, or if $(f_1+f_3-t_1-t_2)=0$. The first two cases give the two lens system, which cannot be a paraxial cloak as shown above. The last case makes $f_2\rightarrow$infinity, which also turns this system into a two lens system.

Although a three lens system cannot be an ideal cloak, it can asymptotically approach one. For simplicity, considering the case with symmetric halves ($f_1=f_3$ and $t_1=t_2$) produces equation (24) from equation (21) and equation (25) from equation (23).

$$f_2=(t_1-f_1)/2, \tag{24}$$

$$2t_1^2/(f_1-t_1)=0. \tag{25}$$

Thus, for $f_1 \gg t_1$, both equation (24) and equation (25) can be satisfied in the limit. Accordingly, a practical three lens paraxial cloaking device can be constructed, for example, such as discussed herein.

Turning now to a four lens system as shown in FIG. **11**. By making the second half of the system symmetric to the first half ($f_1=f_4$, $f_2=f_3$, and $t_1=t_3$), any changes in the path of rays that occur in the first half might be undone in the second half which is a possible strategy to make the device appear absent. Both A=1 and C=0 for such a four lens ABCD matrix can be satisfied by equation (26).

$$t_1=f_1+f_2. \tag{26}$$

With equation (26), the ABCD matrix for the four lens system is given by equation (27).

$$\begin{bmatrix} 1 & f_1(-2t_1^2+f_1(2t_1+t_2))/(f_1-t_1)^2 \\ 0 & 1 \end{bmatrix}. \tag{27}$$

Setting B=(2 t_1+t_2) and solving for t_2 yields equation (28).

$$t_2=2f_2(f_1+f_2)/(f_1-f_2). \tag{28}$$

Thus, an exact solution for equation (5) can be found for a rotationally symmetric lens-only system, using at least four lenses. Using equation (26) and equation (28), the total length of the four lens system is given by equation (29).

$$L=2t_1=t_2=2f_1(f_1+f_2)/(f_1-f_2)/(f_1-f_2). \tag{29}$$

FIG. **12** shows a plot of t_1/f_2 (solid line), t_2/f_2 (dashed line), and L/f_2 (dotted line) as a function of the unit-less parameter $a=f_1/f_2$ on the horizontal axis from equations (26), (28), and (29), for all possible symmetric, four lens, ideal paraxial cloaks, for $a=f_1/f_2$ between −5 and 5 (since these values satisfy equation (5) mathematically). However, even if a device matches the t_1, t_2, and/or L for a given $a=f_1/f_2$ value, this does not guarantee it to be an ideal cloak since the physical feasibility and presence of a non-empty cloaking region must be checked separately. Additionally, it can be seen that when $f_1 \rightarrow -f_2$, the system approaches a one lens system ($t_1=t_2=L=0$). The two extrema for L occur when equation (30) is satisfied.

$$f_1=(1\pm\sqrt{2})f_2. \tag{30}$$

Although these and other solutions may satisfy equation (5) mathematically, checks should be made to ensure that any particular solution contains a non-empty cloaking region and is physically feasible, for it to be a valid cloaking device.

Example Three Lens Cloak

The cloaking region for the lens designs described herein depend on what incident angles, or "field-of-view," are allowed. To assess the size of the cloaking space, ray-trace simulations using CODE V were performed. First, referring to FIG. **13**A, FIG. **13**B, and FIG. **14**, a three lens cloak with symmetric left and right halves was simulated. As described above, a three lens system approaches an ideal paraxial cloak as its length goes to zero. The size of the ray bundle entering the system ("entrance pupil") was set to the first lens diameter in our experimental setup (75 mm). The field-of-view is −3.5 degrees to +3.5 degrees. The cloaking region is between the lenses and is the ring-shaped region where no rays pass. FIG. **13**A and FIG. **13**B compare the final image rays to the original rays near the first lens. For an ideal cloak, these rays would overlap. It can be seen that the angles are similar, and the transverse shifts are not too large. FIG. **13**B shows: (1) incoming on-axis rays **32**-*i***1**, **32**-*i***2** and respective outgoing on-axis rays **32**-*o***1**, **32**-*o***2**; (2) incoming off-axis rays **34**-*i***1**, **34**-*i***2**, **34**-*i***3** and corresponding respective outgoing off-axis rays **34**-*o***1**, **34**-*o***2**, **34**-*o***3**; and (3) incoming off-axis rays **36**-*i***1**, **36**-*i***2**, **36**-*i***3** and corresponding respective outgoing off-axis rays **36**-*o***1**, **36**-*o***2**, **36**-*o***3**.

Plano-convex and plano-concave lenses were used for the three lens cloak. FIGS. **15** through **19** shows images taken during an experimental demonstration in which an object (a wall) was located approximately 2 m from the closest lens in the back. The camera used to take the images was located 5.3 meters away from the front lens and optically zoomed in by 21× (the maximum magnification of the camera). The images were taken from on-axis (FIG. **15**—0 degrees), 0.55 degrees off-axis (FIG. **16**), 0.83 degrees off-axis (FIG. **17**), and 1.11 degrees off-axis (FIG. **18**), by increasing the height of the camera. A ruler was placed near the center diverging lenses. It can be seen that the middle of the ruler is cloaked. Also, the lines of the wall as seen through the cloaking device match the background wall as seen outside of the cloaking device, as expected for a good cloak. FIG. **19** shows a side image of the three lens system experimental prototype.

Example Three Lens Cloak Parameters

For the first and last lenses (**1** and **3**) 200 mm focal length, BK7, 75 mm diameter lenses were used. For the center lens, two −100 mm focal length, BK7, 50 mm diameter lenses were used, back-to-back, to create a lens with focal length of approximately −50 mm. All lenses were catalogue optics from Edmund Optics. From equation (24), $t_1=t_2$ equals approximately 100 mm was obtained. Including the lens thicknesses and the material indices of refraction, t_1 was optimized slightly so that the afocal condition C=0 was closely achieved. Diameter of last lens needs to be >150 mm for all rays to pass (no "vignetting"). For the CODE V simulation, the apertures were not restricted to the actual lens sizes. The aperture stop was the first surface. Aperture diameter sizes (for no vignetting) of the first and second diverging lenses in the center are 54 mm and 61 mm, respectively. Total length of the system is 219 mm.

Example Four Lens Cloak

A four lens 'ideal' paraxial cloak that has symmetric left and right halves was simulated. Because real lens systems produce aberrations that can blur and distort the observed image, 'achromatic doublets,' which combine two lenses as one, were used to correct for chromatic and other aberrations. Equations (26) and (28) were corrected and t_1, t_2, and t_3 ($t_1=t_3$) were calculated. FIG. **20** shows the results of a simulation that used these calculated paraxial values without any additional optimization. The resulting cloaking region is an elongated cylinder between the lenses where the rays are not present.

As stated above, the cloaking systems disclosed herein are scalable. For example, a four lens cloak can be scaled to any suitable size by scaling all radii of curvature, lengths, and entrance pupil by the same factor. FIG. **21** shows ray tracing simulation results on a four lens paraxial cloak that has been scaled up to twice the size of the four lens paraxial cloak of FIG. **20**, thereby obtaining double the cloaking space.

A prototype four lens cloak was constructed using achromatic doublets to reduce aberrations. Photographs of this prototype paraxial cloak are shown in FIGS. **22** through **26**.

FIG. **22** shows a side profile view of the prototype four lens cloaking device. The grids on the wall were 1.9 m from the closest lens to the back. The camera was 3.1 m away from the front lens, but optically zoomed in by 21×. The images were taken from −0.65 degrees off-axis (FIG. **23**), on-axis (FIG. **24**), at 0.47 degrees off-axis (FIG. **25**), and 0.95 degrees off-axis (FIG. **26**) viewing angles, by changing the height of the camera. A ruler was placed behind the second doublet from the front. The middle of the ruler is cloaked near the center of the device. In particular, the grids on the wall are clear for all colors, have minimal distortion, and match the shifts of the background grids for all the angles.

Example Four Lens Cloak Parameters

For the first and last lenses (**1** and **4**), 200 mm focal length, 50 mm diameter achromatic doublets composed of BK7 and SF2 glasses were used. For the center two lenses (**2** and **3**), 75 mm focal length, 50 mm diameter achromatic doublets composed of SF11 and BAF11 glasses were used. All doublets were off-the-shelf catalogue optics from Thorlabs and had antireflection coating in the visible spectrum. For the CODE V simulations, the aperture sizes were not restricted, so as to ensure no vignetting. The aperture stop was the first surface. Diameters of the second, third, and last doublets need to be >33 mm, 51 mm, and 112 mm, respectively, for no vignetting. Total length of the system is 910 mm.

Extending Paraxial Cloaking to Include the Full Field

We now discuss non-limiting examples of paraxial cloaks that work for the full-field (matched amplitude and phase). FIG. **32** schematically shows one example of a full field paraxial cloak. In FIG. **32**, the image from the cloaking device is the same as the object. Propogation of light rays can be described by an 'ABCD' matrix. n is the index of refraction of the ambient medium. L is the longitudinal length of the device along the center z-axis. E_1 and E_2 are the input and output fields, respectively, at $z=z_1$ and z_2. In this example, phase matching is achieved with a flat plate with index n_c and length L_c.

In some instances, the examples of paraxial full-field cloaking described in this section satisfy all but the omnidirectionality of an 'ideal' cloaking device. In some instances, this 'paraxial' formalism can work for up to +/−30°, which is quite practical for many cases where the cloaked object is not placed immediately before an observer. Although we discuss below the propagation of a monochromatic field, since an arbitrary field of light can be written as a linear superposition of monochromatic waves, our systems extend to broadband without loss of generality.

Duan et al. recently provided phase matching with their unidirectional cloaking system based off of geometric optics (see R. Duan, E. Semouchkina, and R. Pandey, "Geometric optics-based multiband cloaking of large objects with the wave phase and amplitude preservation," Optics Express 22, 27193-27202 (2014)). They provided a heuristic reason why rays that pass through the edge of their optical system may match the phase of those rays that pass through the center instead, for their particular setup with split lenses. They then simulated phase-matched cloaking for discretely separated micro-waves to mm-waves. Here, we provide for and analytically show phase matching for general paraxial optical systems, including continuously multidirectional cloaking systems. Embodiments of our phase matching systems utilize formula given by Siegman and others (see A. E. Siegman, Lasers (University Science Books, Sausalito, C A, 1986)), for propagation of any paraxial field through a generalized paraxial optical system. The resulting formula is proved using Fermat's principle and Huygens' integral, by accounting for the optical path lengths of all rays.

Field propagation based off of Huygens' principle of wavelet propagation, is effective and widely used in diffraction theory and Fourier optics. We first assume that the ambient medium is spatially uniform with index of refraction n, and that the optical system of interest is rotationally symmetric for simplicity (so can be described by a 2×2 ABCD matrix) (see FIG. **32**). Non-uniform medium or non-rotationally symmetric systems are also envisioned, and can be derived from here.

For rotationally symmetric two-dimensions, and no limiting apertures, Huygens' integral in the Fresnel (or, paraxial) approximation is given by equation (31) (see S. A. Collins, "Lens-system diffraction integral written in terms of matrix optics," J. Opt. Soc. Am. 60, 1168-1177 (1970)):

$$\tilde{E}_2(x_2, y_2) = \frac{ie^{-ik_0L_0}}{B\lambda_0}\int\int_{-\infty}^{\infty}\tilde{E}_1(x_1, y_1)\exp\left\{-i\frac{\pi}{B\lambda_0}\left[A(x_1^2+y_1^2)-2(x_1x_2+y_1y_2)+D(x_2^2+y_2^2)\right]\right\}dx_1dy_1. \tag{31}$$

In equation (31), A, B, C, Dare the coefficients of the ABCD matrix. $L_0=\Sigma_i n_i L_i$ is the on-axis optical path length, where each ith optical element has index of refraction n_i and physical thickness L_i along the longitudinal, center axis (z). λ_0 and λ_0 are the wavelength and wavevector in free space. $\tilde{E}_1$, $\tilde{E}_2$ are the complex, spatial amplitude of the input ($z=z_1$) and output ($z=z_2$) field distributions, respectively (E_1, E_2 in FIG. **32**, but without the $e^{+i\omega t}$ harmonic time dependence).

In some of the embodiments described in previous sections, we stated that an 'ideal' cloaking device simply replicates the ambient medium throughout its volume, and so its ABCD matrix is given by equation (32):

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}_{ideal\ cloak} = \begin{bmatrix} 1 & L/n \\ 0 & 1 \end{bmatrix}. \tag{32}$$

Thus, the propogated field for an 'ideal' full-field cloak is given by equation (33):

$$\tilde{E}_2^{cloak}(x_2, y_2) = \frac{ine^{-ik_0nL}}{L\lambda_0}\int\int_{-\infty}^{\infty}\tilde{E}_1(x_1, y_1)\exp\left\{-i\frac{n\pi}{L\lambda_0}\left[(x_1^2+y_1^2)-2(x_1x_2+y_1y_2)+(x_2^2+y_2^2)\right]\right\}dx_1dy_1. \tag{33}$$

A ray optics cloak embodiment satisfies equation (32). By comparing equations (31) and (33), we then see that a ray optics cloak can be a full-field cloak if $e^{-ik_0L_0}=e^{ik_0nL}$, which may be the case when $k_0L_0=k_0nL$ (absolute phase matching), or when $L_0\equiv nL \pmod{\lambda_0}$ (phase-matching to integer multiples of 2π). The significance of these conditions is that they allow for phase-matched, full field cloaking for any incoming fields within the paraxial approximation. In some embodiments, the phase-matching condition only needs to be satisfied once for a given optical system, and then all ray directions and positions, or any field distribution ($\tilde{E}_1$) will exit if traversed through a cloaked ambient space. Note that a ray optics cloak (equation (32)) will usually be phase-matched to integer multiples of 2π with a full-field cloak for multiple, but discretely separated, wavelengths automatically. However, we can do better and match it for a continuous, broad bandwidth by satisfying the phase-matching to integer multiples of 2π condition with appropriate dispersion control.

One method for broadband phase matching is to add a thin, flat plate to a ray optics cloak, anywhere between the background object(s) and the observer. Since it is "thin" and flat, the original ABCD matrix (equation (32)) will be unchanged and only the $e^{-ik_0 L_0}$ factor outside the integral of equation (31) will be affected. Let $L'=\Sigma_{i=1}^{N} L_i$ be the total length of the original ray optics cloak (so $L=L_c+L'$), where N is the number of original optical elements. So $L_0 \rightarrow n_c L_c + \Sigma_{i=1}^{N} n_i L_i$ in Eq. (31), and $nL \rightarrow n(L_c+L')$ in Eq. (33). Here, n_i, L_i are the index of refraction and physical longitudinal length, respectively, for the i^{th} optical element, and n_c, L_c are likewise for the correcting thin plate. It may be shown that a plate is "thin" when $|L_c/L'| \ll 1$ and $|L_c/L'| \ll |n_c/n|$. With our phase-correcting plate, the phase-matching to integer multiples of 2π condition is rearranged to write the dispersion relation of n_c:

$$n_c(\lambda_0, m, L_c) = n(\lambda_0) + \frac{1}{L_c}\left\{m\lambda_0 + \sum_{i=1}^{N}[n(\lambda_0) - n_i(\lambda_0)]L_i\right\}. \tag{34}$$

$m \in \mathbb{Z}$ is any integer, with infinite but discrete choices.

There are infinitely many combinations of L_c and in that are possible for $n_c((\lambda_0)$, m, $L_c)$. Ultimately, the choice of which to use should depend on physically realizable n_c's. A few such solutions, that phase-corrects a four lens cloak described in J. S. Choi and J. C. Howell, "Paraxial ray optics cloaking," Optics Express 22, 29465-29478 (2014), are shown in FIG. **33**, in which the dispersion relations of the refractive index for these plates are shown for various values of m and L_c (mm) from Eq. (34), in air. In this example, for simplicity, we assumed that the cloaking system is placed in air, with $n=n_{air}=1$ for all wavelengths, and we ignored any coatings. The lens coatings can be modeled as additional thin plates as needed. We also only consider the visible spectrum (400-700 nm, for our discussion). A thicker compensating flat plate can reduce the required dispersion range, but this also affects the imaging quality, so we have purposely limited its thickness for this particular example.

Many of the solutions for positive refractive indices require anomalous dispersion, as shown in FIG. **33**. For the purposes of cloaking, at least in some implementations, such dispersion for broadband spectrum that have low losses are desired to imitate ambient space properly. This is similar to the finite bandwidth cloak made of anisotropic layers, as suggested by Kildishev et al., which also required strong anomalous dispersion combined with loss compensation. Costa and Silveirinha have suggested using nanowire metamaterial to provide such anomalous dispersion, and they numerically calculated their index of refraction to be near 2.9~3.1 for the entire visible spectrum. See J. T. Costa and M. G. Silveirinha, "Achromatic lens based on a nanowire material with anomalous dispersion," Opt. Express 20, 13915-13922 (2012). They can achieve these low loss, broadband, anomalous dispersion properties by utilizing the collective, spatial properties of metamaterials (called 'spatially dispersive' materials). This allows the ability to move beyond the high loss and narrow band properties of typical transparent materials, which stem from the Kramers-Kronig relations. In addition, Theisen and Brown have experimentally demonstrated anomalous dispersion for 500~1,000 nm, with Gallium implanted Silicon pads. These have indices of refraction near 2 or 4, each with variations of about 1 over the spectrum, depending on the doping level.

Negative-index metamaterials are good candidates for phase-correction as well for some implementations. The utilization of metamaterials was to be expected, since we expanded ray optics cloaking to the field cloaking aspect of transformation optics. Much progress is being made, both theoretically and experimentally, for creating negative index materials for broadband optical frequencies. Some examples of refractive index values demonstrated experimentally include between −3 and 0 for microwave frequencies in two-dimensions, n=0.63 at 1,200 nm to n=−1.23 at 1,775 nm in a low loss, 3D bulk material, and n=1 to −7.5 for 1.1-2.4 micron wavelengths.

By relaxing only omnidirectionality for an 'ideal' cloak, we have shown how to match the phase for the whole visible spectrum in some implementations. The phase-matching plate may require negative index metamaterials or anomalous dispersion in some instances, which are broadband and low loss, but current research has shown much progress in this regard. We had shown that building a 3D, broadband, macroscopic cloak, that works for the visible spectrum, can be fairly "easy" for ray optics in the small angle limit, and have extended this to the full-field using recently developed materials. As with typical lens designs, we expect that extending such cloaks to large angles will be possible.

It is interesting to note that the paraxial full-field cloak we presented does not require anisotropy, though being 3D, macroscopic, and broadband. Anisotropy seems to be a requirement when creating an omnidirectional cloak, from a paraxial cloak, not necessarily a property of 3D or field cloaks alone.

Potential Applications

The paraxial cloaking devices and related methods described herein may be applicable in many different fields, for example, such as in communications, transportation, military technologies, and medical devices. Additionally, the paraxial cloaking devices describe herein can alternatively be used to make visible an object that is obscured by another object. For example, a paraxial cloaking device can be used to view an internal organ or tissue that is hidden behind another internal organ or tissue that cannot be moved to make the hidden object directly visible. An enlarged cloaking device could allow portions of a building to be "see-through" on the outside, allow drivers to see directly behind the vehicle even if the space behind the driver is blocked (by objects or people, or the vehicle itself as in the case of semi-trucks), or furniture and objects inside a building to be invisible for interior design effects. A paraxial cloak can also hide a satellite orbiting the earth from a range of viewing angles, as well as a tank flanked by trees on each side, or offices or people on one end of a hallway. Some of these applications are shown in FIG. **31**.

In fact, the ABCD matrix for equation (5) can be solved for any waves or "rays" that can be described by similar matrices, to find an ideal "cloaking" device for such "rays." These include seismic waves, sound (acoustic waves), water waves, etc., not just optical rays. A cloaking device for such waves can allow water waves to not damage rigs by effectively cloaking the rigs, reduce damage from tsunamis in likewise manner, or allow certain geographical regions or buildings to not be heavily damaged by earthquakes by diverting the earthquake waves. These and other applications are shown in FIG. **31**.

Other variations are within the spirit of the present invention. For example, other variations including three and/or four lens cloaks that are split in half and connected the other way, or even combined, so as to make cloaking regions that cloak the center axis region (these can create two-dimensional cloaks, or can be manufactured for three-dimensions by rotating the split or combined lens designs completely around the center axes). FIG. **27** shows CODE V simulation results for a split three lens paraxial cloak. The simulation results show: (1) the path of incoming on-axis rays **32**-*i***1**, **32**-*i***2** and resulting respective outgoing on-axis rays **32**-*o***1**, **32**-*o***2**; (2) the path of incoming off-axis rays **34**-*i***1**, **34**-*i***2** and resulting respective outgoing off-axis rays **34**-*o***1**, **34**-*o***2**; (3) the path of incoming off-axis rays **36**-*i***1**, **36**-*i***2** and resulting respective outgoing off-axis rays **36**-*o***1**, **36**-*o***2**; and (4) a resulting cloaked region in the center of the split three lens paraxial cloak. FIG. **28** shows CODE V simulation results for a combined four lens paraxial cloak. The simulation results show: among other rays, (1) the path of incoming on-axis rays **32**-*i***1**, **32**-*i***2**, **32**-*i***3** and resulting respective outgoing on-axis rays **32**-*o***1**, **32**-*o***2**, **32**-*o***3**; (2) the path of incoming off-axis rays **34**-*i***1**, **34**-*i***2** and resulting respective outgoing off-axis rays **34**-*o***1**, **34**-*o***2**; (3) the path of incoming off-axis rays **36**-*i***1**, **36**-*i***2** and resulting respective outgoing off-axis rays **36**-*o***1**, **36**-*o***2**; and (4) resulting cloaked regions in the center of the combined four lens paraxial cloak, as well as the outer region/shell. Equation (5) can also be applied to five lenses or more, or for any optical system with arbitrary number of elements (lenses, mirrors, or anything else that can be described with an ABCD matrix). Also, lenses can be replaced by Fresnel lenses that can be larger, thinner, and lighter, though possibly with lesser image quality than regular lenses and/or achromatic lenses.

Thus, while the invention is susceptible to various modifications and alternative constructions, certain illustrated embodiments thereof are shown in the drawings and have been described above in detail. It should be understood, however, that there is no intention to limit the invention to the specific form or forms disclosed, but on the contrary, the intention is to cover all modifications, alternative constructions, and equivalents falling within the spirit and scope of the invention, as defined in the appended claims.

The use of the terms "a" and "an" and "the" and similar referents in the context of describing the invention (especially in the context of the following claims) are to be construed to cover both the singular and the plural, unless otherwise indicated herein or clearly contradicted by context. The terms "comprising," "having," "including," and "containing" are to be construed as open-ended terms (i.e., meaning "including, but not limited to,") unless otherwise noted. The term "connected" is to be construed as partly or wholly contained within, attached to, or joined together, even if there is something intervening. Recitation of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate value is incorporated into the specification as if it were individually recited herein. All methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. The use of any and all examples, or exemplary language (e.g., "such as") provided herein, is intended merely to better illuminate embodiments of the invention and does not pose a limitation on the scope of the invention unless otherwise claimed. No language in the specification should be construed as indicating any non-claimed element as essential to the practice of the invention.

Preferred embodiments of this invention are described herein, including the best mode known to the inventors for carrying out the invention. Variations of those preferred embodiments may become apparent to those of ordinary skill in the art upon reading the foregoing description. The inventors expect skilled artisans to employ such variations as appropriate, and the inventors intend for the invention to be practiced otherwise than as specifically described herein. Accordingly, this invention includes all modifications and equivalents of the subject matter recited in the claims appended hereto as permitted by applicable law. Moreover, any combination of the above-described elements in all possible variations thereof is encompassed by the invention unless otherwise indicated herein or otherwise clearly contradicted by context.

All references, including publications, patent applications, and patents, cited herein are hereby incorporated by reference to the same extent as if each reference were individually and specifically indicated to be incorporated by reference and were set forth in its entirety herein.

What is claimed is:

1. A paraxial cloaking device having a cloaking volume and a reference optical axis, the device comprising:

an optical input receiving light rays; and

an optical output from which a continuous range of directions of the received light rays exit the paraxial cloaking device, the optical output being offset from the optical input, the cloaking volume being disposed between the optical input and the optical output,

wherein, for the received light rays having incoming directions non-parallel to the reference optical axis up to a first angle, each of the received light rays exits the cloaking device at the optical output substantially aligned with the respective received light ray and does not pass through the cloaking volume,

wherein the paraxial cloaking device has a unity magnification factor and is afocal.

2. The cloaking device of claim **1**, wherein the first angle is 3.5 degrees.

3. The cloaking device of claim **1**, wherein the first angle is 5 degrees.

4. The cloaking device of claim **1**, wherein the first angle is 15 degrees or more.

5. The cloaking device of claim **1**, wherein the cloaking device provides rotationally symmetric cloaking and comprises at least three lenses.

6. The cloaking device of claim **5**, wherein each of the three lenses is centered on the reference optical axis.

7. The cloaking device of claim **5**, wherein the clocking device comprises four lenses.

8. The cloaking device of claim **7**, wherein the four lenses are centered on the reference optical axis.

9. The cloaking device of claim **7**, wherein at least one of the four lenses comprises an achromatic doublet.

10. The cloaking device of claim **1**, wherein the cloaking device imparts an optical transformation to the received light rays defined by an ABCD matrix, wherein A=1, B=L/n, C=0, and D=1; L being a length between the optical input and the optical output, n being an index of refraction for the surrounding/ambient medium, before and/or after, the cloaking device.

11. The cloaking device of claim **1**, comprising:

a first lens centered on the reference optical axis;

a first mirror tilted from the reference optical axis;

a curved second mirror;

a third mirror tilted from the reference optical axis; and

a second lens centered on the reference optical axis,

wherein, the optical input comprises the first lens, the optical output comprises the second lens, and a light ray passing through the cloaking device follows an optical propagation path, the second mirror being disposed along the optical propagation path between the first and second lenses, the first mirror being disposed along the optical propagation path between the first lens and the second mirror, and the third mirror being disposed along the optical propagation path between the second mirror and the second lens.

12. The cloaking device of claim **11**, wherein:

the first and second lenses have the same focal length;

the first lens and the first mirror are separated by a distance equal to a distance separating third mirror and the second lens; and

the first mirror and the second mirror are separated a distance equal to a distance separating the second mirror and the third mirror.

13. The cloaking device of claim **1**, comprising:

a first lens centered on the reference optical axis;

a first mirror tilted from the reference optical axis;

a second lens;

a second mirror;

a third lens;

a third mirror tilted from the reference optical axis; and

a fourth lens centered on the reference optical axis,

wherein, the optical input comprises the first lens, the optical output comprises the fourth lens, and a light ray passing through the cloaking device follows an optical propagation path, the second mirror being disposed along the optical propagation path between the first and fourth lenses, the first mirror being disposed along the optical propagation path between the first lens and the second mirror, the third mirror being disposed along the optical propagation path between the second mirror and the fourth lens, the second lens being disposed along the optical path between the first and second mirror, and the third lens being disposed along the optical path between the second and third mirrors.

14. The cloaking device of claim **13**, wherein:

the first and fourth lenses have the same focal length;

the first lens and the first mirror are separated by a distance equal to a distance separating third mirror and the fourth lens;

the first mirror and the second lens are separated a distance equal to a distance separating the third lens and the third mirror;

the second and third lenses have the same focal length; and

the second lens and the second mirror are separated a distance equal to a distance separating the second mirror and the third lens.

15. A method of designing the cloaking device of claim **1**, comprising:

configuring a candidate cloaking device; and

calculating an ABCD matrix for the candidate cloaking device,

wherein the candidate cloaking device is configured such that A=1, B=L/n, C=0, and D=1; L being a length between the optical input and the optical output, n being an index of refraction for the surrounding/ambient medium, before and/or after, the cloaking device.

16. The method of claim **15**, further comprising adjusting at least one of a parameter or a position of at least one optical component of the candidate cloaking device so as to compensate for a thickness of at least one optical component of the candidate cloaking device.

17. The method of claim **15**, further comprising:

tracing at least one ray through the candidate cloaking device to assess a deviation between the location and direction of the ray prior to being received by the candidate cloaking device and after exiting the candidate cloaking device; and

adjusting at least one of a parameter and a position of at least one optical component of the candidate cloaking device based on the deviation assessment so as to reduce the deviation.

18. A method for designing a second cloaking device having a desired cloaking volume, the method comprising:

selecting a first cloaking device in accordance with claim **1**;

determining a scale factor indicative of a size difference between the desired cloaking volume and the cloaking volume of the first cloaking device; and

determining configuration parameters of the second cloaking device by scaling corresponding configuration parameters of the first cloaking device by the scale factor.

19. The cloaking device of claim **1**, wherein the device does not include a metamaterial optical component.

20. The cloaking device of claim **1**, wherein the device does not include a non-isotropic optical component.

21. The cloaking device of claim **1**, wherein the device does include a metamaterial optical component.

22. The cloaking device of claim **1**, further comprising a phase matching element.

23. The cloaking device of claim **22**, wherein the phase matching element comprises a flat plate having at least one index of refraction and a longitudinal length.

24. The cloaking device of claim **23**, wherein the phase matching element comprises an anomalous dispersion element.

25. The cloaking device of claim **23**, wherein the phase matching element comprises a metamaterial.

26. The cloaking device of claim **25**, wherein the index of refraction is at least one negative index of refraction.

27. The cloaking device of claim **1**, wherein the optical output comprises a profile and an axis, wherein the received light rays do not travel outside the profile of the optical output when viewed along the axis of the optical output.

28. The cloaking device of claim **1**, wherein, for the received light rays having incoming directions non-parallel to the reference optical axis up to the first angle, each of the received light rays exits the cloaking device at the optical output at an angle equal to an angle in which the received light ray entered the cloaking device.

29. The cloaking device of claim **1**, wherein, for the received light rays having incoming directions non-parallel to the reference optical axis up to the first angle, each of the received light rays exits the cloaking device at the optical output at a shifted position relative to a position in which the received light ray entered the cloaking device, the shifted position being equal to a tangent of an angle in which the received light ray entered the cloaking device multiplied by a length of the cloaking device.

(57) **ABSTRACT**

A method and apparatus is disclosed herein for harvesting ambient energy. In one embodiment, an energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

SYSTEM FOR AMBIENT ENERGY HARVESTING

FIELD OF THE INVENTION

Embodiments of the present invention relate to the field of wireless power transfer; more particularly, embodiments of the present invention relate to radio-frequency (RF) energy harvesting devices that harvest ambient RF energy and store the received RF energy.

BACKGROUND OF THE INVENTION

Next generation sensor networks may be powered by energy harvesting techniques to avoid requiring battery maintenance. Energy harvesting is a process by which energy is derived from external sources (e.g., radio frequency energy, solar power, thermal energy, wind energy, salinity gradients, or kinetic energy), captured and stored.

Energy may be harvested from radio frequency signals propagating wirelessly. With RF harvesting, wireless energy comes from a radio frequency transmitting device that is some distance away from a device that harvests energy from the radio frequency transmission. Properties of an energy harvester include its ability to harvest energy efficiently from available RF signals, its ability to store the harvested energy efficiently with minimal storage loss, and its ability to make the stored energy available to meet the voltage, current, and duty cycle requirements of a desired application.

One of the more popular forms of RF used today is Wi-Fi (also referred to as IEEE 802.11a/b/g/n etc.) communications. Today, most Wi-Fi communications are in the 2.4 GHz and 5.8 GHz frequency bands and there are many local area networks that are based on Wi-Fi in which access points enable Wi-Fi clients to gain access to networks such as the Internet. Furthermore, the 2.4 GHz and 5.8 GHz bands also support other networking standards, such as Zigbee and Bluetooth, and other proprietary networks, each transmitting energy by communicating in this same frequency band. Additionally there are other frequency bands that support different communication protocols, each of which transmit energy when they are communicating. These include, for example, digital television (DTV) and Global System for Mobile Communications (GSM) signals.

In a traditional RFID-like setup the RFID readers (interrogators) usually deliver RF power as a continuous wave (CW), i.e. a sinusoidal signal of a particular frequency. In contrast to systems designed for use with continuous wave (CW) signals such as RFID, some RF energy harvesters are designed for use with non-CW signals such as WiFi and GSM. These waveform aware harvesters include ambient energy harvesters that harvest signals of opportunity that are already present in the environment. For these types of harvesters, the system designer must work around the waveforms and power levels that are already present in the environment.

SUMMARY OF THE INVENTION

A method and apparatus is disclosed herein for harvesting ambient energy. In one embodiment, an energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be understood more fully from the detailed description given below and from the accompanying drawings of various embodiments of the invention, which, however, should not be taken to limit the invention to the specific embodiments, but are for explanation and understanding only.

DETAILED DESCRIPTION OF THE PRESENT INVENTION

A system for ambient energy harvesting and method for doing the same are described. In one embodiment, the energy harvesting system includes three DC reservoirs to store energy generated from ambient radio frequency (RF) input signals. These reservoirs are coupled together in a cascaded fashion to provide DC energy to a load.

In one embodiment, the ambient RF energy harvester is part of a sensor/tag device and is used to provide energy to one or more components of the sensor/tag device such as, for example, the sensor, a controller, a communication unit a processing device, etc.

In the following description, numerous details are set forth to provide a more thorough explanation of the present invention. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the present invention.

Some portions of the detailed descriptions which follow are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description, discussions utilizing terms such as "processing" or "computing" or "calculating" or "determining" or "displaying" or the like, refer to the action and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (electronic) quantities within the computer system's registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

The present invention also relates to apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, such as, but is not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs), EPROMs, EEPROMs, magnetic or optical cards, or any type of media suitable for storing electronic instructions, and each coupled to a computer system bus.

The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the present invention is not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the invention as described herein.

A machine-readable medium includes any mechanism for storing or transmitting information in a form readable by a machine (e.g., a computer). For example, a machine-readable medium includes read only memory ("ROM"); random access memory ("RAM"); magnetic disk storage media; optical storage media; flash memory devices; etc.

One Embodiment of a Sensor Device

FIG. **1** is a block diagram of one embodiment of a sensor device. The sensor device may be part of a tag. Referring to FIG. **1**, sensor device **100** comprises an ambient radio-frequency (RF) energy harvester **101**, an ultra-low-power (ULP) sensor **102** (e.g., temperature, light, humidity, etc.), a micro-controller **103**, and a communication unit **104**. Although not shown, sensor device **100** includes one or more antennas. The antennas may be part of communication unit **104** or may be separate, such as in the case of an antenna used to harvest energy.

In one embodiment, RF energy harvester **101** harvests ambient RF power to run ultra-low power tags and/or sensors **102**, micro-controller **103**, and/or communication unit **104**, based on received RF input energy received by an antenna (not shown) of sensor device **100**. There are a number of sources of ambient RF power, including, but not limited to WiFi, DTV and GSM signals. Other sources of ambient RF power include, for example, toys, proprietary communication protocols, and even stray energy leakage from devices, such as microwave ovens. The antenna receiving the RF energy input may be part of communication unit **104** or a separate antenna. The antenna(s) may be designed to receive the energy in multiple frequency bands, or there may be separate antenna(s) for these different frequency bands.

In one embodiment, sensor **102** comprises an ultra-low-power (ULP) sensor and/or tag and micro-controller **103** comprises an ultra-low-power (ULP) micro-controller. Sensor **102** may comprise a temperature sensor, a light sensor, a motion sensor, air flow sensor, image sensor, accelerometer, gyroscope, gas detector, microphone, atmospheric pressure sensor, humidity sensor, mechanical pressure sensor, etc. In one embodiment, sensor **102**, as a ULP sensor, has a power requirement of 1-20 uW and a duty cycle of 1% to 10% (where the duty cycle varies in response to available energy over a period of time or the specific sensing needs, usually seconds to hours).

In one embodiment, micro-controller **103** performs control operations and/or processing for the sensor device **100**. In one embodiment, controller **103** is responsive to and receives sensor data from sensor **102** and provides it to communication unit **104** for transmission (e.g., wireless transmission) from device **100**. Controller **103** may also log sensor data for a time, and transmit the entire log to communication unit **104** for transmission later. Note that in this case the sensing rate and the communication rate can be different.

Communication unit **104** provides a communication mechanism for sensor device **100**. In one embodiment communication unit **104** is a wireless communication unit. In one embodiment, communication unit **104** has an RF transmission along with an antenna for receiving and transmitting RF signals, including RF signals transmitted with an access point or other locally positioned device.

In one embodiment, the ambient RF energy harvester is optimized for overall efficiency and a minimum of start-up power. These optimizations improve the range at which energy can be usefully harvested and improve the number of places where ambient energy is practical, particularly in view of the fact that ambient RF energy levels are small and often bursty (traffic-dependent), rectified voltages are very low (<100 mV) at typical ranges, and typical Complementary Metal Oxide Semiconductor (CMOS) loads such as MCU etc. require 800+ mV to operate.

An energy harvester and method for performing energy harvesting are described. In one embodiment, the energy harvester converts incident radio frequency (RF) energy, or ambient RF energy, to direct current energy. In one embodiment, the energy harvester comprises: a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy; a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage; a DC/DC boost converter coupled to the first energy reservoir to convert the first voltage to a second voltage; a second reservoir coupled to the DC/DC converter to store energy at the second voltage, where the second voltage is greater than the first voltage; and a third reservoir (e.g., a longer-term energy storage device such as a low-leakage capacitor or battery, etc.) coupled to the second reservoir to receive energy transferred from the second reservoir periodically.

In one embodiment, the RF rectifier comprises one selected from a group consisting of: a Schottky diode, a P-N junction diode, a diode-connected field effect transistor, and a tunnel diode.

In one embodiment, the first reservoir comprises a capacitor with a capacitance value determined at least in part by the envelope of the received RF energy. In one embodiment, the first reservoir comprises a capacitor having a value based on stored energy above a threshold voltage given ambient RF input power and a duty cycle of the input power. In another embodiment, the first reservoir comprises a first capacitor and the second reservoir comprises a second capacitor, wherein capacitance of the second capacitor is approximately equal to a product of the first capacitor capacitance times a square of a ratio of an expected value of the second voltage divided by an expected value of the first voltage.

In one embodiment, the second reservoir comprises an inductor used to boost the voltage, wherein energy stored in the inductor is approximately equal to energy stored in the first reservoir.

In one embodiment, the DC/DC boost converter comprises a self-excited oscillator. In one embodiment, the self-excited oscillator comprises a transistor coupled to a transformer. In one embodiment, the frequency of the self-excited oscillator is controlled at least in part by an envelope of the received RF energy. In one embodiment, the DC/DC converter is a switch mode converter with switching intervals controlled at least in part by an envelope of the received RF energy.

In one embodiment, the third reservoir is coupled to the second reservoir via a switch, which is closed periodically to transfer energy from the second reservoir to the third reservoir. In one embodiment, the switch is controlled at least in part by the envelope of the received RF energy. In one embodiment, the third reservoir is coupled to a load, and the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load. In one embodiment, the third reservoir has an energy storage capacity that is greater than an energy storage capacity of the second reservoir.

FIG. **2** is a block diagram of one embodiment of an RF energy harvester. Referring to FIG. **2**, RF energy harvester **200** comprises RF rectifier **201**, a first direct current (DC) reservoir (storage) **202**, a boost converter and second reservoir **203**, a third reservoir **204**, and control logic **205**.

RF rectifier **201** receives ambient RF energy input received from an antenna and rectifies the RF energy to produce a DC voltage.

First DC reservoir **202** stores the voltage generated from the rectified RF signals received by device **100**. In one embodiment, reservoir **202** comprises a capacitor. In one embodiment, the size (value) of the capacitor that is selected for use is based on the stored energy above a voltage threshold for the ambient RF input power.

Second DC reservoir **203** receives the voltage and increases the voltage. To increase the voltage, second DC reservoir **203** includes a DC/DC converter. In one embodiment, the DC/DC converter comprises a boost converter which includes a self-excited oscillator for operation. The self-excited oscillator includes a junction field effect transistor (JFET) coupled with a transformer. In one embodiment, the amount of the boost conversion is a function of the input energy, and the DC/DC converter is designed to maximize the output voltage as a function of input voltage in this low-energy environment. FIG. **7** illustrates one embodiment of a self-excited oscillator. Referring to FIG. **7**, the embodiment of the self-excited oscillator includes an input (Rectified RF_IN), an output (BOOST_OUT), capacitors C**1** (100 μF); optional C**2** (100 pF); and C**3** (0.1 μF), transistors Q**6** and Q**1**, a transformer (T**1**), and a resistor R**2** (10K) coupled as shown. FIG. **8** illustrates one embodiment of a charger schematic that receives the output of the boost converter, such as, for example, the one shown in FIG. **7**. Referring to FIG. **8**, the embodiment of the charger schematic includes an input (BOOST_OUT), an output to a battery (Battery+ and Battery−), diodes D**2** for preventing a low-voltage drop; D**3** (1N4148); D**4** (1N4148); D**5** (BAT43), capacitors C**4** (0.1 μF) and C**5** (0.01 μF), transistors Q**3**, Q**4**, and Q**5**, and resistors R**3** (10K), R**4** (100K), and R**5** (10K).

The upconverted voltage from the DC/DC converter is stored in a storage device of second reservoir **203**. In one embodiment, second reservoir **203** uses a capacitor to store the upconverted voltage. In another embodiment, second reservoir **203** uses an inductor to store the upconverted voltage, but this is a much shorter-term storage option.

When the energy stored in second reservoir **203** reaches a certain level, the energy is transferred to a third reservoir (not shown). Thus, the transfer occurs periodically at a rate determined by the amount of input energy. In one embodiment, the third reservoir comprises a battery, a capacitor, a supercap, etc. The third reservoir provides DC energy to a load.

In one embodiment, the load comprises a sensor, processor or microcontroller, and/or a communication unit. In one embodiment, the DC voltage from the third reservoir is able to run the load, while the voltage produced by rectifier **201** would not be able to do so.

Control logic **205** controls the energy harvesting process. In one embodiment, control logic **205** comprises a separate unit that generates control signals to control each of the reservoirs **202-3203**. In another embodiment, the control is distributed through various discrete gating components such that a separate control unit is not necessary but the function is still performed.

FIG. **3** is another more detailed block diagram of one embodiment of an RF energy harvester. Referring to FIG. **3**, RF energy harvester **300** comprises RF rectifier **301**, a first direct current (DC) reservoir (storage) **302**, second reservoir **303**, and a third reservoir **304**. In one embodiment, the input to RF rectifier **301** is an RF input from an antenna on the sensor device. RF rectifier **301** converts the RF input signals to a voltage. In one embodiment, the voltage may range between 10 mV and 500 mV. The voltage is stored in reservoir **302**. In one embodiment, reservoir **302** comprises a ceramic capacitor 1 uF to 100 uF or more.

In one embodiment, the stored energy from reservoir **302** is transferred to second reservoir **303** via a transistor **311**, self-gated as the voltage rises in reservoir **302**. In one embodiment, second reservoir **303** comprises a boost converter **303**A. The boost converter **303**A operates to upconvert the voltage stored in reservoir **302** and store that upconverted voltage into reservoir **303**B.

The energy stored in second reservoir **303** is transferred to third reservoir **304**. In one embodiment, third reservoir **304** comprises a tantalum capacitor, supercap 100 uF to 1 F or a battery. In one embodiment, transistor **312** (e.g., a FET) couples second reservoir **303** to third reservoir **304**, which turns on when second reservoir **303** reaches an optimal voltage. In one embodiment, transistor **312** is controlled at least in part by the envelope of the received RF energy such that when the voltage stored in reservoir **303**B reaches a certain watermark level, transistor **312** closes/turns on and the energy is transferred. In one embodiment, through the selection of high gate-threshold transistors, the voltage can build up fairly high in reservoir **303** (as much as 1-2V) before the transistor **312** closes/turns on. Transistor **312** closes/turns on automatically when the gate threshold of the transistor design is reached in reservoir **303**. As soon as transistor **312** closes/turns on, the energy is transferred from reservoir **303** into reservoir **304**, thus depleting the energy in reservoir **303**, and the gate threshold falls below the watermark level and the transistor **312** closes/opens again. The process then repeats when the voltage in reservoir **303** becomes sufficiently high.

Note that transistor **311** and **312** may be replaced with other types of switches.

Waveform Aware Harvesting

In one embodiment, the RF waveform harvester comprises a RF to DC converter that is optimized for use with non-continuous wave (CW) signals. In another embodiment, the RF waveform harvesters are waveform aware and are able to perform ambient energy harvesting based on a waveform model, where the available RF energy is in the form of communication waveforms of a variety of types. Examples of commonly-harvested ambient RF energy sources with non-continuous wave signals include, but are not limited to, digital television (DTV) broadcasts, cellular base station transmissions (e.g., GSM, Code Division Multiple Access (CDMA)), Wi-Fi transmissions, etc.

For example, in one embodiment, WiFi is the communications waveform that is the ambient form of energy to be harvested. WiFi is bursty and has low amplitude compared to other sources of energy, where a bursty signal has a high peak to average ratio over ms to s time scale. For example, some WiFi signals have WiFi transmission burst times on the order of 1 ms. For a bursty signal, the harvester can only contribute energy to the reservoir capacitor (C_x) when the ambient source is transmitting.

FIG. **4** illustrates a diode-based harvester schematic. Referring to FIG. **4**, in one embodiment, the harvester is designed to be well matched at input power levels below −20 dBm where the majority of ambient Wi-Fi signals are expected to fall. Thus, harvester is characterized both in terms of its input match from 2.4 GHz to 2.5 GHz, as well as for harvesting efficiency at its maximum power point (MPP). Harvesting efficiency is defined as the ratio of input RF power at the harvester to harvested DC power at the load (η=PDC/PRF).

The purpose of capacitor C_X in FIG. **4** is to store charge for any subsequent active electronic circuitry. In one embodiment, typical circuit power-up threshold voltages V_{TH} equals 0.8 V, as is typical for CMOS logic in commodity processes. In another embodiment, the power-up threshold voltages V_{TH} equals 50 mV, as is typical for ultra-low startup voltage boost converters using JFETs. Alternatively, specially doped CMOS transistors, floating gate devices, or Silicon on Insulator (SOI) transistors may be capable of operation down to voltages approaching V_{TH}=50-100 mV as well.

If the usable energy is defined as the portion of the stored energy above some threshold voltage V_{TH}, the following describes how to find a value of C_X given the ambient RF input power and the signal's duty cycle. This is based on the maximum power point curve for the harvester, the typical burst timings for the ambient signal of interest (e.g., WiFi with some traffic model), and a time domain response for the harvester as a function of C_X. Thus, in one embodiment, the storage capacitor selection C_X is optimized on the time scale of network traffic for the signal being harvested.

FIG. **5** illustrates a diode output circuit model. Because the diode is a non-linear device, the power delivered to the load varies dramatically with load impedance. The Maximum Power Point Tracking (MPPT) circuit functions as a load impedance converter to maximize the power delivered to the load, given a particular nonlinear operating point.

Referring to FIG. **5**, the diode output model consists of an open-circuit voltage V_{source} along with a nonlinear source resistance R_{source}. The pair, V_{source}, R_{source}, represents a fixed operating point at maximum power-point (MPP). The load resistance R_{load} includes any leakage currents in C_X as well as the quiescent current of the active circuitry attached to the harvester. In other words, the load impedance R_{load} is chosen a priori based on the MPP of the harvester at a given ambient signal level (the maximum power point of the harvester given the input power). Using this model, only the effect of varying C_X (not other system conditions) is considered.

FIG. **6**A illustrates the usable energy stored in capacitor C_X during one transmission burse of duration T_p. Referring to FIG. **6**A, the usable energy in C_X is represented as the shaded portion of the curve above the voltage threshold and below the voltage across the capacitor.

FIG. **6**B illustrates examples of good and bad choices of C_X. If C_X is too large, the active circuitry will never be powered because the input energy is insufficient to generate voltage above the threshold. On the other hand, if C_X is minimized, little energy will be stored in the reservoir C_X and the runtime of the active circuitry will not extend beyond the transmission intervals of the RF source. Referring to FIG. **6**, harvesters 'A' and 'B' represent different choices for C_X with the same conditions otherwise. In harvester A, C_X looks appropriate as the output voltage exceeds V_{TH} during each burst, while in harvester B, C_X is too big and the output voltage never exceeds V_{TH} so there is no usable energy.

An expression is derived for the useful-energy-maximizing reservoir capacitance C_X as a function of ambient RF signal duty cycle and the load impedance RL at a diode harvester's maximum power point. The expression may be used to calculate the usable energy as a function of the known parameters and the unknown capacitance C_X.

The total energy in C_X may be expressed as follows:

$$E = \frac{1}{2}CV^2$$

where C is the capacitance and V is the terminal voltage of C_X. It is assumed that the energy stored on the capacitor is only usable when the capacitor voltage is above the desired threshold V_{TH}. The usable energy is thus the difference between the stored energy at the end of an RF transmission (at time t=T_p) and the stored energy when C_X is charged only to V_{TH} and is expressed as follows:

$$E_{usable} = \frac{1}{2}C\left[V_{T_p}^2 - V_{th}^2\right]$$

where V_{Tp} is the terminal voltage on C_X at the end of an RF transmission (e.g., at the end of each burst) of duration T_p and is expressed as:

$$V_{T_p} = V_{src}(1 - e^{-T_p/R_L C})$$

By substitution, the equation for the usable energy may be re-written in terms of C and the known values of R_L, V_{TH} and T_p as follows:

$$E_{usable} = \frac{1}{2}CV_{T_p}^2\left[e^{-\frac{2T_p}{R_L C}} - 2e^{-\frac{T_p}{R_L C}} + \left(1 - \left(\frac{V_{th}}{V_{T_p}}\right)^2\right)\right]$$

The equation may be solved for E_{usable} as a function of C_X.

Thus, a new class of RF energy harvesters, referred to herein as waveform aware harvesters, have been described. These RF energy harvesters are RF to DC converters that are optimized for their performance with non-CW signals.

Whereas many alterations and modifications of the present invention will no doubt become apparent to a person of ordinary skill in the art after having read the foregoing description, it is to be understood that any particular embodiment shown and described by way of illustration is in no way intended to be considered limiting. Therefore, references to details of various embodiments are not intended to limit the scope of the claims which in themselves recite only those features regarded as essential to the invention.

We claim:

1. An energy harvester to convert incident radio frequency (RF) energy associated with an RF signal to direct current energy, the energy harvester comprising:

a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy;

a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage;

a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage;

a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and

a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically and coupled to a load, wherein the third reservoir comprises a capacitor having a capacitance value chosen to control an amount of usable energy stored in the third reservoir as a function of an RF transmission duration, the impedance of the load, and a threshold voltage, the usable energy being a portion of the stored energy above the threshold voltage.

2. The energy harvester defined in claim **1** wherein the third reservoir is coupled to the second reservoir via a first switch, the first switch being closed periodically to transfer energy from the second reservoir to the third reservoir.

3. The energy harvester defined in claim **2** wherein the first switch is controlled at least in part by an envelope of the received RF energy signal.

4. The energy harvester defined in claim **1** wherein the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load.

5. The energy harvester defined in claim **1** wherein the DC/DC converter comprises a self-excited oscillator.

6. The energy harvester defined in claim **5** wherein frequency of the self-excited oscillator is controlled at least in part by an envelope of the received RF energy signal.

7. The energy harvester defined in claim **1** wherein the DC/DC converter comprises a boost converter.

8. The energy harvester defined in claim **1** wherein the first reservoir comprises a capacitor with a capacitance determined at least in part by an envelope of the received RF energy signal.

9. The energy harvester defined in claim **1** wherein the DC/DC converter is a switch mode converter with switching intervals controlled at least in part by an the envelope of the received RF energy signal.

10. The energy harvester defined in claim **1** wherein the RF rectifier comprises one or more diodes selected from a group consisting of: a Schottky diode, a P-N junction diode, a diode-connected field effect transistor, and a tunnel diode.

11. The energy harvester defined in claim **1** wherein the third reservoir has an energy storage capacity that is greater than an energy storage capacity of the second reservoir.

12. The energy harvester defined in claim **1** wherein the second reservoir comprises an inductor, wherein energy stored in the inductor is approximately equal to energy stored in the first reservoir.

13. The energy harvester defined in claim **1** wherein the capacitance value is chosen to maximize the amount of usable energy stored in the third reservoir as a function of the RF transmission duration, the impedance of the load, and the threshold voltage.

14. An energy harvester to convert incident radio frequency (RF) energy to direct current energy, the energy harvester comprising:

a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy;

a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage;

a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage;

a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and

a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically, wherein the first reservoir comprises a first capacitor and the second reservoir comprises a second capacitor, wherein capacitance of the second capacitor is approximately equal to a product of the first capacitor capacitance times a square of a ratio of an expected value of the second voltage divided by an expected value of the first voltage.

15. A device comprising:

an antenna;

a load; and

an energy harvester coupled to the antenna and the load, wherein the energy harvester comprises

a first RF rectifier to output a first voltage determined by rectified RF energy in response to received RF energy;

a first energy reservoir coupled to the first RF rectifier to store energy at the first voltage;

a DC/DC converter coupled to the first energy reservoir to convert the first voltage to a second voltage;

a second reservoir coupled to the DC/DC converter to store energy at the second voltage, the second voltage being greater than the first voltage; and

a third reservoir coupled to the second reservoir to receive energy transferred from the second reservoir periodically, wherein the third reservoir comprises a capacitor having a capacitance value chosen to control an amount of usable energy stored in the third reservoir as a function of an RF transmission duration, the impedance of the load, and a threshold voltage, the usable energy being a portion of the stored energy above the threshold voltage.

16. The device defined in claim **15** wherein the third reservoir is coupled to the second reservoir via a switch, the switch being closed periodically to transfer energy from the second reservoir to the third reservoir.

17. The device defined in claim **15** wherein the third reservoir is coupled to the load, and wherein the first voltage is insufficient to operate the load directly, and the third voltage is sufficient to operate the load.

18. The device defined in claim **15** wherein the DC/DC converter comprises a boost converter.

19. The energy harvester defined in claim **15** wherein the capacitance value is chosen to maximize the amount of usable energy stored in the third reservoir as a function of the RF transmission duration, the impedance of the load, and the threshold voltage.

(57) **ABSTRACT**

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

This application claims the benefit of U.S. Provisional Application No. 61/889,894, filed 11 Oct. 2013, the disclosure of which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

In some embodiments, the power receiver further comprises an elevated terminal.

In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** illustrates a first exemplary embodiment of a power receiver.

FIG. **2** illustrates a second exemplary embodiment of a power receiver.

FIG. **3** illustrates a third exemplary embodiment of a power receiver.

FIG. **4** illustrates a fourth exemplary embodiment of a power receiver.

FIG. **5** illustrates a fifth exemplary embodiment of a power receiver.

FIG. **6**A is an exploded perspective view of an exemplary ground antenna array for the power receiver.

FIG. **6**B is a perspective view of an assembled ground antenna array before being deployed.

FIG. **6**C is a perspective view of an assembled ground antenna array after being deployed.

FIG. **7**A is a side view of an insertion tool for installing the ground antenna array.

FIG. **7**B is a top view of the insertion tool for installing the ground antenna array.

FIG. **7**C is a bottom view of the insertion tool for installing the ground antenna array.

DETAILED DESCRIPTION

Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral **10**. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1-200 Hertz. For example, the resonant transformer **30** may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**,**100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **85**. It should be appreciated that the electrical ground **85** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about 10 and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allanson transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part #TC 103-17-125). An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40** of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

The pulse generator **65** comprises a square wave generator **70** and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required. The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. a Filter capacitor **120** removes unwanted frequencies from the DC current. The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

FIG. **5** illustrates a power converter **10** according to another embodiment. The power converter **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

FIGS. **6A-6C** illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6**B. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270** extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6**B illustrates the ground antenna array **200** before deployment. FIG. **6**C illustrates the ground antenna array in a deployed configuration.

Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected to a ground terminal disposed below the surface of the earth;

an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer, said impulse generator comprising:

a signal generator for generating a low voltage signal;

a step-up transformer for converting the low voltage signal to a high voltage signal;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage signal from the step-up transformer; and

a power conversion circuit connected to a secondary winding of the resonant transformer to convert electrical current flowing through the secondary winding to a desired form.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformers is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro-resonant transformer.

4. The power receiver of claim **1** further comprising an elevated terminal, and wherein the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

5. The power receiver of claim **4** wherein the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

6. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

7. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

8. The power receiver of claim **1** further comprising multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

9. The power receiver of claim **8** wherein the resonant transformers have different resonant frequencies.

10. The power receiver of claim **9** wherein the resonant frequencies of the resonant transformers are all below 200 Hz.

11. The power receiver of claim **8** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

12. A ground terminal for a power receiver, said ground terminal comprising:

a ground shaft configured for insertion beneath the surface of the earth;

a hollow cylinder surrounding the ground shaft and having a plurality of openings; and

a plurality of ground wires connected at one end to the ground shaft said ground wires being wound around the ground shaft and having free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

(57) **ABSTRACT**

Disclosed are various embodiments for energy harvesting by circuitry of a node in a network. The node operates in a communication mode that includes communicating, via an RF transceiver, data with another node in the network. The node includes an energy storage device that provides power for the node. The node switches, via an RF switch, from said communication mode to an energy harvest mode. The energy harvest mode includes receiving RF emissions accessible to the node via an antenna. The RF emissions are converted to DC electrical energy, and the DC energy is stored in the energy storage device.

FIG. 5

RF ENERGY HARVESTING BY A NETWORK NODE

BACKGROUND

A communications module for a gas or water meter (or any other battery-powered utility device) must be able to support a battery life of 15-20 years. This is primarily achieved through the use of efficient energy-storage batteries as well as by minimizing the power consumption of the communications module (radio). In order to minimize power consumption, the radio may spend most of its time in a low-power "sleep" mode, waking up on some periodic basis to communicate any data with its network and then returning to sleep.

Replacing exhausted batteries in numerous such devices deployed in operation is a time-consuming and difficult task. Increasing the usable life-span of the batteries in these metering devices can produce significant savings in time and money for utility operators.

SUMMARY

Various aspects of the present invention relate to capturing ambient radio frequency (RF) emissions in order to supplement the energy stored by a node, such as a utility meter that may be deployed as part of an advanced metering infrastructure (AMI) system. In one implementation, the node operates in a communication mode that includes communicating, via an RF transceiver, data with another node in the network. The node includes an energy storage device, such as a battery, that provides power for the node. In various embodiments, the node may not be connected to an external source of power.

The node uses an RF switch in order to switch from the communication mode to an energy harvest mode. The mode switch may occur as a result of the node also entering a low-energy sleep mode and/or having no additional data to be communicated via the network. The energy harvest mode includes receiving RF emissions accessible to the node via an antenna and does not attempt to decode the RF emissions. The node converts the RF emissions to direct current (DC) energy and stores the DC energy in the energy storage device. The RF emissions may be converted to DC energy using a rectifier. The node may switch back to the communication mode based in part upon having data to be transmitted, data scheduled to be received, and/or other possible circumstances.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the present disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, with emphasis instead being placed upon clearly illustrating the principles of the disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a drawing of a networked environment according to various embodiments of the present disclosure.

FIG. **2** is a block diagram of an illustrative example of a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **3** is a flowchart illustrating one example of RF harvesting functionality implemented in a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **4** is a flowchart illustrating another example of RF harvesting functionality implemented in a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **5** is a block diagram that provides another example illustration of a node employed in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

DETAILED DESCRIPTION

The techniques disclosed herein are directed to a node capturing ambient RF emissions in order to supplement the energy provided to the node by an energy storage device. The node may use an antenna to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, and unlicensed industrial, scientific and medical (ISM) bands (900 MHz and 2.4 GHz). For example, research studies have shown an ambient RF energy density of between −60 and −14 dB/m^2 in typical urban environments, all within the 685 MHz to 3.5 GHz frequency range. In these studies, the most energy was found to be in the 1.8-1.9 GHz band.

A node, such as used in a meter for utility service (e.g. electricity, water or gas) as part of an AMI (advanced metering infrastructure) network, can incorporate one or more wideband antennas tuned for all or a portion of these frequency bands. The wideband antenna would collect or "harvest" the RF energy, which could then be converted to a DC electrical energy by, for example, an RF/microwave rectifier circuit. The DC output of the rectifier would then be stored in an energy storage device of the node, such as a battery or supercapacitor, via a charging circuit. The energy stored in the energy storage device would then provide DC power for the node during its operation. While the amount of energy harvested may not be equivalent to the energy consumed by the node during all stages of operation, the energy may be used to supplement the energy stored in the energy storage device.

As defined herein, a "node" includes an intelligent device capable of performing functions related to distributing messages in a mesh network. In one system, a node can be a meter located at a facility, such as a house or apartment, that measures the consumption of a utility such as gas, water, or electric power. Such a meter can be part of an RF network used for AMI. Other examples of nodes include a router, collector or collection point, host computer, hub, or other electronic device that is attached to a network and is capable of sending, receiving, or forwarding information over a communications channel.

A node can contain several components that enable it to function within implementations of the present invention. For example, a node can include a radio that can enable it to communicate with like nodes and/or other devices in the mesh network. The radio of each node may have a programmable logic controller (PLC)-like device that can enable the radio to function like a computer, carrying out computer and command functions to provide implementations of the present invention described herein. A node may also include a storage medium for storing information related to communication with other nodes. Such storage mediums can include a memory, a floppy disk, CD-ROM, DVD, or other storage devices located internal to the node or accessible by the node via a network, for example. A node may also include a crystal oscillator (i.e. a clock) to provide timekeeping and an energy storage device (e.g. a battery) to provide back-up power. Some nodes may be powered only by an energy storage device.

With reference to FIG. **1**, shown is an exemplary illustration of a mesh network that may be employed as part of an AMI or other metering network. The head-end system **103** controls the metering network by communicating through the network **106**. The network **106** that the head-end system **103** may utilize to communicate to a node **109** may include devices such as other nodes, **110-112**, collectors **115**, routers **118**, and possibly other devices. Communication may proceed utilizing any appropriate protocol and any appropriate network configuration. Protocols used by the network **106** include, but are not limited to the IEEE 802.15.4, PRIME, G3, and/or TCP/IP protocols. Several nodes **109-112** may transmit data to a router **118**. The router **118**, in turn, may route data to a collector **115** in the network **106**. A collector may receive data from multiple routers. The collector **115** communicates with the head-end system **103**. The head-end system may receive and send information to multiple collectors.

The nodes, such as the node **109**, may be meters that are usually in geographically dispersed locations such as homes or businesses. The meters are used to monitor a utility resource such as electricity, water, or natural gas and to measure the usage of the resource. Some meters may be smart meters that support a variety of service commands. These service commands may allow utilities to disconnect, or limit service remotely or manually at the meter. In addition, some meters may store an event log that contains entries of functions the meter has performed. Service commands may originate from the head-end system **103** and are sent via the network **106** to nodes **109-112**.

To support functionality and continuous operation of a meter, the node **109** may include an energy storage device either as a supplemental/backup power source or as a sole power source. In order to reduce the electrical power consumed during operation the node **109**, may use an antenna to capture the energy from ambient RF emissions **121** from various commercially used RF bands, such as cellular, broadcast television, and ISM bands. While harvesting RF emissions in this manner has the benefit of reducing electrical power consumed from other sources, it can be especially critical when the node is reliant upon an energy storage device as the only power source for an extended period.

In some embodiments, the node **109** may begin harvesting energy from the ambient RF emissions **121** during periods in which no communications are expected to occur. During such periods, a portion of the components of the node **109** may enter a low-energy "sleep" mode in order to conserve electrical power. In these embodiments, an RF switch may be used to switch the one or more antennas of the node from the transceiver circuitry to the circuitry used for RF harvesting.

In other embodiments, a node may harvest energy from the ambient RF emissions **121** independent of communications of node through the use of antenna(s) and other circuitry that is separate from the communications circuitry. In these embodiments, the RF harvesting may occur continuously or when a threshold is met associated with the energy storage device of the node (e.g. the energy level is less than 50% of capacity).

In addition, a node may communicate with other devices of the network **106** in order to request these devices to begin transmitting RF emissions in order to augment the ambient RF emissions **121** received by the node. Such a scenario would typically occur with, for example, a battery-powered node requesting that another device powered from an external source provide additional RF emissions. A request for additional RF emissions may occur, for example, when the energy storage device of the node reaches a threshold, when the ambient RF emissions **121** are insufficient, and/or based upon other criteria.

Referring next to FIG. **2**, shown is a block diagram of an illustrative embodiment of the node **109** which implements the RF harvesting techniques. The node **109** includes one or more antennas, represented by the antenna **201**, which may be used to transmit and receive communications for the node **109**, as well as capture RF emissions to be stored as energy. The design of the antenna **201** may be affected by the RF band(s) at which the node communicates in a network **106** and the RF band(s) at which the node will capture RF emissions. For example, the antenna **201** may include an antenna for the ISM 900 MHz bands, in addition to another antenna used for the 1.8-1.9 GHz RF bands.

In this illustrative embodiment of FIG. **2**, the antenna **201** is connected to an RF switch **203** that connects the antenna **201** to either the transceiver signal path or the RF harvesting signal path. As described previously, other arrangements allowing, for example, simultaneous RF harvesting and data communication may also be possible. In FIG. **2**, the transceiver signal path includes the circuitry used for communicating data to and from the node **109**, while the RF harvesting signal path includes the circuitry used to charge the energy storage device using the captured RF emissions. A node may be said to operate in a "communication mode" while the transceiver signal path is selected via the RF switch, and in an "RF harvest mode" while the RF harvesting signal path is selected.

The RF harvesting signal path comprises a rectifier **205**, charging circuitry **207**, an energy storage device **209**, and/or other components not described in detail herein. The rectifier **205** is an RF/microwave rectifier that converts the energy from the captured RF emissions as input to a DC electrical energy output. The rectifier may be implemented using, for example, diodes.

The charging circuitry **207** may adjust the voltage or other components of the DC output from the rectifier **205** to a form suitable for storing in the energy storage device **209**. The energy storage device **209** represents one or more energy storage devices such as a battery, capacitor, supercapacitor, and/or other electrical energy storage devices. In the embodiment shown in FIG. **2**, the energy storage device **209** is the only source of power for the node **109**, though other configurations that use an external power source in conjunction with a local energy storage device are possible.

A microcontroller **211** is responsible for managing the operation and data communications of the node **109**. To this end, the microcontroller **211** manages the RF switch **203** and the transceiver circuitry **213** that facilitates transmission and reception of data along the transceiver signal path. In some embodiments, the microcontroller **211** may also monitor charging of the energy storage device **209** via the charging circuitry **207**. The various components of the node **109** may receive electrical power from the energy storage device **209**. The electrical power from the energy storage device **209** may be adjusted by the voltage regulator **215** in order to accommodate the electrical needs of disparate electrical components. For example, the voltage regulator **215** may adjust the 3.0 V output from the energy storage device to the 3.45 V required by the microcontroller **211**.

Referring next to FIG. **3**, shown is a flowchart that provides an exemplary implementation of the RF harvesting operations for a method **300** of a node, such as the node **109**, according to various embodiments. It is understood that the flowchart of FIG. **3** provides merely an example of the many different types of functional arrangements that may be employed to implement the RF harvesting operations of the method **300** as described herein. The operations depicted in the flowchart of FIG. **3** illustrate the transition of the node from operating in a communication mode to operating in a harvest mode. As described previously, variations of this implementation may also be possible allowing a node to communicate via a network, while concurrently capturing energy from ambient RF emissions.

Beginning with block **303**, the node determines whether to begin the RF harvest mode or to remain in the communication mode. The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node had no current data communication taking place, nor any that were expected, some components (e.g. the transceiver circuitry) of the node might enter a low-power “sleep mode,” at which time the node may also enter a harvest mode to capture RF emissions. Similarly, if the node detected that the energy level of the energy storage device was, for example, below a threshold of 50%, the node may begin RF harvesting instead of taking place in non-essential communications.

If the node determines that RF harvesting is not ready to begin, then execution of the method **300** returns to block **303**. Alternatively, if RF harvesting should be initiated, in block **306**, the node may place the RF switch in a position to provide received RF emission to the RF harvesting signal path. Thereafter, in block **309**, the node may receive RF emissions via the one or more antennas of the node. The node may use the antenna(s) to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, ISM bands (900 MHz and 2.4 GHz), and/or other possibilities. For example, research studies have shown an ambient RF energy density of between −60 and −14 dB/m2 in typical urban environments, all within the 685 MHz to 3.5 GHz frequency range. In these studies, the most energy was found to be in the 1.8-1.9 GHz band.

Next, in block **312**, the rectifier of the node converts the energy from the various received RF emissions to DC electrical energy. Then, in block **315**, the DC energy output from the rectifier may be stored in the energy storage device of the node through use of charging circuitry. The charging circuitry may be used to monitor and adjust the characteristics of the DC energy used to charge the energy storage device, monitor the current capacity of the energy storage device, and/or other possible re-charging functions. In some embodiments, some or all of the DC energy output from the rectifier may be used to directly power, at least in part, one or more other components of the node such as, for example, the microcontroller. During periods of low power usage, such as during the sleep mode, the energy collected from RF emissions may be sufficient to provide a substantial portion of the power consumed by various components (e.g. the microcontroller).

Subsequently, in block **318**, the node determines whether to continue the RF harvesting (i.e. harvest mode). The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node detected that the energy level of the energy storage device was at a threshold of 100%, the node may no longer need to continue to harvest the energy since no more capacity exists to store it. Similarly, if the node is scheduled to soon report a utility meter reading to a head-end system, the node may end the harvest mode in order to deliver the scheduled communication data.

In the event that the RF harvesting is determined to continue, execution of the method **300** returns to block **309**. Alternatively, if it is determined that the current period of RF harvesting should end, in block **321**, the node places the RF switch in a position that connects the antenna to the transceiver signal path in order to enable the node to communicate with other devices in the network. Thereafter, execution of the method **300** may return to block **303**.

Moving on to FIG. **4**, shown is a flowchart that provides another exemplary implementation of the RF harvesting operations for a method **400** of a node, such as the node **109**, according to various embodiments. It is understood that the flowchart of FIG. **4** provides merely an example of the many different types of functional arrangements that may be employed to implement the RF harvesting operations of the method **400** as described herein. The operations depicted in the flowchart of FIG. **4** illustrate the transition of the node from operating in a communication mode to operating in a harvest mode, where the node requests a neighboring node to supplement the ambient RF emissions by generating additional RF emissions to be harvested by the node. As described previously, variations of this implementation may also be possible allowing a node to communicate via network, while concurrently capturing energy from ambient RF emissions.

Beginning with block **403**, the node determines whether to begin the RF harvest mode or to remain in the communication mode. The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated.

If the node determines that RF harvesting is not ready to begin, then execution of the method **400** returns to block **403**. Alternatively, if RF harvesting should be initiated, in block **404**, the node may communicate with one or more neighboring nodes in the network to request that the node(s) produce additional RF emissions in order to supplement the energy received during the harvest mode. Typically, a node would make a request to neighboring nodes known to have an external power source (i.e. power supplied through the electric utility grid) or that otherwise have a substantial reserve of energy available.

Then, in block **406**, the node may place the RF switch in a position to provide received RF emission to the RF harvesting signal path. Thereafter, in block **409**, the node may receive RF emissions via the one or more antennas of the node. The neighboring node(s) responding to the request for addition RF emissions may produce a continuous waveform (CW) of RF energy that may be received by the requesting node, as well as other nodes in the area. The node may use the antenna(s) to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, ISM bands (900 MHz and 2.4 GHz), and/or other possibilities.

Next, in block **412**, the rectifier of the node converts the energy from the various received RF emissions to DC electrical energy. Then, in block **415**, the DC energy output from the rectifier may be stored in the energy storage device of the node through use of charging circuitry. The charging circuitry may be used to monitor and adjust the characteristics of the DC energy used to charge the energy storage device, monitor the current capacity of the energy storage device, and/or other possible re-charging functions.

Subsequently, in block **418**, the node determines whether to continue the RF harvesting (i.e. harvest mode). The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node detected that the energy level of the energy storage device was at a threshold of 100%, the node may no longer need to continue to harvest the energy since no more capacity exists to store it. Similarly, if the node is scheduled to soon report a utility meter reading to a head-end system, the node may end the harvest mode in order to deliver the scheduled communication data.

In the event that the RF harvesting is determined to continue, execution of the method **400** returns to block **409**. Alternatively, if it is determined that the current period of RF harvesting should end, in block **421**, the node places the RF switch in a position that connects the antenna to the transceiver signal path in order to enable the node to communicate with other devices in the network. As an optional step, in block **424**, once the node has returned to the communication mode, the node may transmit a notification to the neighboring nodes indicating that the node is no longer in harvest mode and that the transmission of additional RF emission is no longer needed by the node. In some implementations, the neighboring nodes producing additional RF emissions as requested in block **404** may do so for a predefined period of time. Thereafter, execution of the method **400** may return to block **403**.

Next, in FIG. **5**, shown is another block diagram depicting an example of a node **109-112** used for implementing the techniques disclosed herein. The node **109-112** can include a processing device **502**. Non-limiting examples of the processing device **502** include a microprocessor, an application-specific integrated circuit ("ASIC"), a state machine, or other suitable processing device. The processing device **502** can include any number of processing devices, including one. The processing device **502** can be communicatively coupled to computer-readable media, such as memory device **504**. The processing device **502** can execute computer-executable program instructions and/or access information respectively stored in the memory device **504**. In some implementations, the processor **502** and memory **504** may be incorporated as components of a microcontroller, such as the microcontroller **211**.

The memory device **504** can store instructions that, when executed by the processing device **502**, cause the processing device **502** to perform operations described herein. The memory device **504** may be a computer-readable medium such as (but not limited to) an electronic, optical, magnetic, or other storage device capable of providing a processor with computer-readable instructions. Non-limiting examples of such optical, magnetic, or other storage devices include read-only ("ROM") device(s), random-access memory ("RAM") device(s), magnetic disk(s), magnetic tape(s) or other magnetic storage, memory chip(s), an ASIC, configured processor(s), optical storage device(s), or any other medium from which a computer processor can read instructions. The instructions may comprise processor-specific instructions generated by a compiler and/or an interpreter from code written in any suitable computer-programming language. Non-limiting examples of suitable computer-programming languages include C, C++, C#, Visual Basic, Java, Python, Perl, JavaScript, and the like.

The nodes **109-112** can include a bus **506** that can communicatively couple one or more components of the node **109-112**. Although the processor **502**, the memory **504**, and the bus **506** are depicted in FIG. **5** as separate components in communication with one another, other implementations are possible. For example, the processor **502**, the memory **504**, and the bus **506** can be components of printed circuit boards or other suitable devices that can be disposed in a node **109-112** to store and execute programming code.

The nodes **109-112** can also include network interface device **508**, such as may be implemented by the transceiver circuitry **213**. The network interface device **508** can be a transceiving device configured to establish one or more of the wireless communication links via an antenna **201**. A non-limiting example of the network interface device **508** is an RF transceiver and can include one or more components for establishing a communication links to other nodes **109-112** in the mesh network **106**.

Numerous specific details are set forth herein to provide a thorough understanding of the claimed subject matter. However, those skilled in the art will understand that the claimed subject matter may be practiced without these specific details. In other instances, methods, apparatuses, or systems that would be known by one of ordinary skill have not been described in detail so as not to obscure claimed subject matter.

Some portions are presented in terms of algorithms or symbolic representations of operations on data bits or binary digital signals stored within a computing system memory, such as a computer memory. These algorithmic descriptions or representations are examples of techniques used by those of ordinary skill in the data processing arts to convey the substance of their work to others skilled in the art. An algorithm is a self-consistent sequence of operations or similar processing leading to a desired result. In this context, operations or processing involves physical manipulation of physical quantities. Typically, although not necessarily, such quantities may take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared or otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to such signals as bits, data, values, elements, symbols, characters, terms, numbers, numerals, or the like. It should be understood, however, that all of these and similar terms are to be associated with appropriate physical quantities and are merely convenient labels. Unless specifically stated otherwise, it is appreciated that throughout this specification discussions utilizing terms such as "processing," "computing," "calculating," "determining," and "identifying" or the like refer to actions or processes of a computing device, such as one or more computers or a similar electronic computing device or devices, that manipulate or transform data represented as physical electronic or magnetic quantities within memories, registers, or other storage devices, transmission devices, or display devices of the computing platform.

The system or systems discussed herein are not limited to any particular hardware architecture or configuration. A computing device can include any suitable arrangement of components that provide a result conditioned on one or more function calls. Suitable computing devices include multipurpose microprocessor-based computer systems accessing stored software that programs or configures the computing system from a general-purpose computing apparatus to a specialized computing apparatus implementing one or more aspects of the present subject matter. Any suitable programming, scripting, or other type of language or combinations of languages may be used to implement the teachings contained herein in software to be used in programming or configuring a computing device.

Aspects of the methods disclosed herein may be performed in the operation of such computing devices. The order of the blocks presented in the examples above can be varied—for example, blocks can be re-ordered, combined, and/or broken into sub-blocks. Certain blocks or processes can be performed in parallel.

The use of "adapted to" or "configured to" herein is meant as open and inclusive language that does not foreclose devices adapted to or configured to perform additional tasks or steps. Additionally, the use of "based on" is meant to be open and inclusive, in that a process, step, calculation, or other action "based on" one or more recited conditions or values may, in practice, be based on additional conditions or values beyond those recited. Headings, lists, and numbering included herein are for ease of explanation only and are not meant to be limiting.

While the present subject matter has been described in detail with respect to specific aspects thereof, it will be appreciated that those skilled in the art, upon attaining an understanding of the foregoing, may readily produce alterations to, variations of, and equivalents to such aspects. Accordingly, it should be understood that the present disclosure has been presented for purposes of example rather than limitation, and does not preclude inclusion of such modifications, variations, and/or additions to the present subject matter as would be readily apparent to one of ordinary skill in the art.

Therefore, the following is claimed:

1. A method for energy harvesting by circuitry of a node in a network, comprising:

operating in a communication mode comprising:

communicating, via a radio frequency (RF) transceiver, data with another node in the network, wherein the node comprises an energy storage device that provides power for the node; and

in response to occurrence of a time period during which no further data communication is scheduled in the node, switching, via an RF switch in the node, from said communication mode to an energy harvest mode comprising:

receiving RF emissions accessible to the node via an antenna;

providing the received RF emissions to a rectifier;

converting the RF emissions to direct current (DC) energy, wherein said converting is implemented using the rectifier; and

storing the DC energy in the energy storage device.

2. The method of claim **1**, further comprising switching back to the communication mode when the node determines additional data needs to be transmitted or received by the node, the communication mode further comprising:

receiving additional RF emissions accessible to the node via the antenna; and

decoding the additional data from the additional RF emissions.

3. The method of claim **1**, wherein the node is a utility meter deployed as part of an advanced metering infrastructure (AMI) system.

4. The method of claim **1**, wherein the energy storage device is the only source of electrical power for the node during operation.

5. The method of claim **1**, wherein said switching to the energy harvesting mode is based at least in part upon the node determining that a sleep mode can begin.

6. The method of claim **1**, wherein said receiving RF emissions comprises receiving a plurality of RF signals in one or more RF bands.

7. A node, comprising:

a processor;

an antenna;

a radio frequency (RF) switch for switching connectivity to the antenna;

an energy storage device that provides power for the node;

a rectifier;

an RF transceiver for communicating on a network accessible to the node; and

a memory configured by a management application executed in the node, the management application comprising logic causing the node to:

operate in an energy harvest mode comprising:

receiving RF emissions accessible to the node via the antenna;

converting, via the rectifier, the RF emissions to direct current (DC) energy; and

storing the DC energy in the energy storage device; and

in response to occurrence of a time period during which data communication is scheduled in the node, switch, via the RF switch, from said energy harvest mode to a communication mode comprising:

communicating, via the RF transceiver, data with another node in the network, wherein said communicating uses power from the energy storage device.

8. The node of claim **7**, wherein said switch to the communication mode occurs when the node determines additional data needs to be transmitted or received by the node.

9. The node of claim **8**, wherein the additional data needs to be transmitted or received by the node on a periodic basis.

10. The node of claim **7**, wherein the management application further comprises logic to request the other node in the network to transmit additional RF emissions to the node.

11. The node of claim **7**, wherein the network is a wireless mesh network of a plurality nodes that includes the node.

12. The node of claim **7**, wherein the RF transceiver operates in one or more of the industrial, scientific and medical (ISM) RF bands.

13. The node of claim **12**, wherein said receiving RF emissions comprises receiving a plurality of RF signals in one or more RF bands, a portion of the one or more RF bands being outside the ISM RF bands.

14. A non-transitory computer-readable medium embodying a program executable by a processor of a node, comprising:

code for operating the node in a communication mode comprising:

communicating, via a radio frequency (RF) transceiver, data with another node in a network, wherein the node comprises an energy storage device that provides power for the node;

code for operating the node in an energy harvest mode comprising:

receiving RF emissions accessible to the node via an antenna;

providing the received RF emissions to a rectifier;

converting the RF emissions to direct current (DC) energy, wherein said converting is implemented using the rectifier; and

storing the DC energy in the energy storage device; and code for switching, via an RF switch in the node, between the modes based upon a determination made in the node, wherein the node switches to the energy harvesting mode in response to occurrence of a time period during which no further data communication is scheduled in the node.

15. The non-transitory computer-readable medium of claim **14**, wherein the node receives electrical power only from the energy storage device in the node.

16. The non-transitory computer-readable medium of claim **15**, wherein the program further comprises code for requesting the other node in the network to transmit additional RF emissions to the node, wherein the other node receives electrical power from an external source.

17. The non-transitory computer-readable medium of claim **14**, wherein the node is a utility meter deployed as part of an advanced metering infrastructure (AMI) system.

18. The non-transitory computer-readable medium of claim **14**, wherein the determination comprises switching to the energy harvest mode based upon a power level of the energy storage device reaching a threshold.

19. The non-transitory computer-readable medium of claim **14**, wherein the determination comprises switching to the energy harvest mode based upon a completion of a scheduled data communication.

(57) **ABSTRACT**

A radio frequency (RF) circuit comprises an antenna operably coupled to receive an RF signal, a power harvesting circuit operable to generate a first power source from the RF signal, a tank circuit coupled to the antenna and a tuning circuit. The tank circuit includes a selectively variable impedance and the tuning circuit is adapted to dynamically vary the selectively variable impedance of the tank circuit based on resonance of the RF circuit and frequency of the RF signal to substantially align the resonance of the RF circuit with the frequency of the RF signal. When the resonance of the RF circuit is substantially aligned with the frequency of the RF signal, the power harvesting circuit generates a second power source from the RF signal such that the second power source is greater than the first power source.

METHOD AND APPARATUS FOR DETECTING RF FIELD STRENGTH

CROSS-REFERENCE TO RELATED APPLICATIONS

The present U.S. Utility Patent Application claims priority pursuant to 35 U.S.C. §120 as a Continuation of U.S. Utility application Ser. No. 14/644,471, entitled "Method and Apparatus for Detecting RF Field Strength", filed 11 Mar. 2015, issuing as U.S. Pat. No. 9,704,085 on 11 Jul. 2017, which is a Continuation of U.S. Utility application Ser. No. 13/209,425, entitled "Method and Apparatus for Detecting RF Field Strength", filed 14 Aug. 2011, now U.S. Pat. No. 9,048,819, issued 2 Jun. 2015, which is a Continuation-In-Part of application Ser. No. 12/462,331, filed 1 Aug. 2009, now U.S. Pat. No. 8,081,043, issued 20 Dec. 2011 ("Related Application"), which is in turn a Division of application Ser. No. 11/601,085, filed 18 Nov. 2006, now U.S. Pat. No. 7,586,385, issued 8 Sep. 2009 ("Related Patent") (collectively, "Related References"). Application Ser. No. 13/209,425 also claims priority pursuant to 35 U.S.C. §119(e) to U.S. Provisional Application No. 61/428,170, filed 29 Dec. 2010, and U.S. Provisional Application No. 61/485,732, filed 13 May 2011. The subject matter of the Related References, each in its entirety, is expressly incorporated herein by reference.

This application is related to application Ser. No. 13/209,420, filed on 14 Aug. 2011, now U.S. Pat. No. 8,749,319, issued 10 Jun. 2014 ("Related Co-application").

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to detecting RF field strength, and, in particular, to detecting RF field strength in a passive RFID system.

2. Description of the Related Art

In general, in the descriptions that follow, we will italicize the first occurrence of each special term of art that should be familiar to those skilled in the art of radio frequency ("RF") communication systems. In addition, when we first introduce a term that we believe to be new or that we will use in a context that we believe to be new, we will bold the term and provide the definition that we intend to apply to that term. In addition, throughout this description, we will sometimes use the terms assert and negate when referring to the rendering of a signal, signal flag, status bit, or similar apparatus into its logically true or logically false state, respectively, and the term toggle to indicate the logical inversion of a signal from one logical state to the other. Alternatively, we may refer to the mutually exclusive Boolean states as logic_0 and logic_1. Of course, as is well known, consistent system operation can be obtained by reversing the logic sense of all such signals, such that signals described herein as logically true become logically false and vice versa. Furthermore, it is of no relevance in such systems which specific voltage levels are selected to represent each of the logic states.

In accordance with our prior invention previously disclosed in the Related References, the amplitude modulated ("AM") signal broadcast by the reader in an RFID system will be electromagnetically coupled to a conventional antenna, and a portion of the current induced in a tank circuit is extracted by a regulator to provide operating power for all other circuits. Once sufficient stable power is available, the regulator will produce, e.g., a power-on-reset signal to initiate system operation. Thereafter, the method disclosed in the Related References, and the associated apparatus, dynamically varies the capacitance of a variable capacitor component of the tank circuit so as to dynamically shift the f_R of the tank circuit to better match the f_C of the received RF signal, thus obtaining maximum power transfer in the system.

In general, the invention disclosed in the Related References focused primarily on quantizing the voltage developed by the tank circuit as the primary means of matching the f_R of the tank circuit to the transmission frequency, f_C, of the received signal. However, this voltage quantization is, at best, indirectly related to received signal field strength. We submit that what is needed now is an effective and efficient method and apparatus for quantizing the received field strength as a function of induced current. It is further desirable to develop this field quantization in a form and manner that is suitable for selectively varying the input impedance of the receiver circuit to maximize received power, especially during normal system operation. Additionally, in light of the power sensitive nature of RFID systems, it is desirable to vary the input impedance with a minimum power loss.

BRIEF SUMMARY OF THE INVENTION

In accordance with the preferred embodiment of our invention, we provide a sensing system for use in an RFID system. In general, the sensing system comprises an RFID tag and an RFID reader. In one embodiment, the RFID tag comprises a tank circuit having a selectively variable impedance; and a tuning circuit adapted to dynamically vary the impedance of the tank circuit, and to develop a first quantized value representative of the impedance of said tank circuit. In one alternate embodiment, the RFID tag comprises a detector circuit adapted to develop a second quantized value as a function of a field strength of a received RF signal. In yet another embodiment, the RFID tag comprises both the tank and tuning circuit, and the detector circuit. In these embodiments, RFID reader is adapted selectively to retrieve one or both of the first and second values, and, preferably, to use the retrieved values to sense changes to an environment to which the RFID tag is exposed

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

My invention may be more fully understood by a description of certain preferred embodiments in conjunction with the attached drawings in which:

FIG. **1** illustrates, in block diagram form, an RF receiver circuit having a field strength detector constructed in accordance with an embodiment of our invention;

FIG. **2** illustrates, in block diagram form, a field strength detector circuit constructed in accordance with an embodiment of our invention;

FIG. **3** illustrates, in block schematic form, a more detailed embodiment of the field strength detector circuit shown in FIG. **2**;

FIG. **4** illustrates, in flow diagram form, the sequencing of operations in the field strength detector circuit shown in FIG. **3**;

FIG. **5** illustrates, in graph form, the response of the field strength detector circuit shown in FIG. **3** to various conditions;

FIG. **6** illustrates, in block schematic form, an RF receiver circuit constructed in accordance with another embodiment of our invention;

FIG. **7** illustrates, in flow diagram form, the sequencing of the operations in the RF receiver circuit shown in FIG. **6**;

FIG. **8** illustrates, in block schematic form, an alternative representation of the impedance represented by the antenna and the tank circuit of the exemplary RFID receiver circuit.

FIG. **9** illustrates, in block schematic form, an alternative exemplary embodiment of the field strength detector circuit shown in FIG. **3**.

FIG. **10** illustrates, in block schematic form, an alternative exemplary embodiment of the field strength detector circuit shown in FIG. **3**.

FIG. **11** illustrates, in block schematic form, an exemplary RFID sub-system containing tag and reader.

In the drawings, similar elements will be similarly numbered whenever possible. However, this practice is simply for convenience of reference and to avoid unnecessary proliferation of numbers, and is not intended to imply or suggest that our invention requires identity in either function or structure in the several embodiments.

DETAILED DESCRIPTION OF THE INVENTION

Shown in FIG. **1** is an RF receiver circuit **10** suitable for use in an RFID application. As we have described in our Related References, an RF signal electromagnetically coupled to an antenna **12** is received via a tank circuit **14**, the response frequency, f_R, of which is dynamically varied by a tuner **16** to better match the transmission frequency, f_C, of the received RF signal, thus obtaining a maximum power transfer. In particular, as further noted in the Related Applications, the RMS voltage induced across the tank circuit **14** by the received RF signal is quantized by tuner **16** and the developed quantization employed to control the impedance of the tank circuit **14**. As also described in the Related References, the unregulated, AC current induced in the tank circuit **14** by the received RF signal is conditioned by a regulator **18** to provide regulated DC operating power to the receiver circuit **10**. In accordance with our present invention, we now provide a field strength detector **20**, also known as a power detector, adapted to develop a field-strength value as a function of the field strength of the received RF signal. As we have indicated in FIG. **1**, our field strength detector **20** is adapted to cooperate with the regulator **18** in the development of the field-strength value. As we shall disclose below, if desired, our field strength detector **20** can be adapted to cooperate with the tuner **16** in controlling the operating characteristics of the tank circuit **14**.

Shown by way of example in FIG. **2** is one possible embodiment of our field strength or power detector **20**. In this embodiment, we have chosen to employ a shunt-type regulator **18** so that, during normal operation, we can use the shunted 'excess' current as a reference against which we develop the field-strength value. In this regard, we use a reference **22** first to develop a shunt current reference value proportional to the shunted current, and then to develop a mirrored current reference value as a function of both the shunted current and a field strength reference current provided by a digitally-controlled current source **24**. Preferably, once the tuner **16** has completed its initial operating sequence, whereby the f_R of the tank circuit **14** has been substantially matched to the f_C of the received signal, we then enable a digital control **26** to initiate operation of the current source **24** at a predetermined, digitally-established minimum field strength reference current. After a predetermined period of time, control **26** captures the mirrored current reference value provided by the current reference **22**, compares the captured signal against a predetermined threshold value, and, if the comparison indicates that the field strength reference current is insufficient, increases, in accordance with a predetermined sequence of digital-controlled increments, the field strength reference current; upon the comparison indicating that the field strength reference current is sufficient, control **26** will, at least temporarily, cease operation.

In accordance with our invention, the digital field-strength value developed by control **26** to control the field strength current source **24** is a function of the current induced in the tank circuit **14** by the received RF signal. Once developed, this digital field-strength value can be employed in various ways. For example, it can be selectively transmitted by the RFID device (using conventional means) back to the reader (not shown) for reference purposes. Such a transaction can be either on-demand or periodic depending on system requirements. Imagine for a moment an application wherein a plurality of RFID tag devices are distributed, perhaps randomly, throughout a restricted, 3-dimensional space, e.g., a loaded pallet. Imagine also that the reader is programmed to query, at an initial field strength, all tags "in bulk" and to command all tags that have developed a field-strength value greater than a respective field-strength value to remain silent'. By performing a sequence of such operations, each at an increasing field strength, the reader will, ultimately, be able to isolate and distinguish those tags most deeply embedded within the space; once these 'core' tags have been read, a reverse sequence can be performed to isolate and distinguish all tags within respective, concentric 'shells' comprising the space of interest. Although, in all likelihood, these shells will not be regular in either shape or relative volume, the analogy should still be apt.

In FIG. **3**, we have illustrated one possible embodiment of our field strength detector **20***a*. In general, we have chosen to use a shunt circuit **18***a* to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. Shunt regulators of this type are well known in the art, and typically use zener diodes, avalanche breakdown diodes, diode-connected MOS devices, and the like.

As can be seen, we have chosen to implement current reference **22** in the form of a current mirror circuit **22***a*, connected in series with shunt circuit **18***a* between nodes **28** and **30**. As is typical, current mirror circuit **22***a* comprises a diode-connected reference transistor **32** and a mirror transistor **34**. If desired, a more sophisticated circuit such as a Widlar current source may be used rather than this basic two-transistor configuration. For convenience of reference, we have designated the current shunted by shunt circuit **18***a* via reference transistor **32** as i_R; similarly, we have designated the current flowing through mirror transistor **34** as i_R/N, wherein, as is known, N is the ratio of the widths of reference transistor **32** and mirror transistor **34**.

We have chosen to implement the field strength current source **24** as a set of n individual current sources **24***a*, each connected in parallel between the supply node **28** and the mirror transistor **34**. In general, field strength current source **24***a* is adapted to source current at a level corresponding to an n-bit digital control value developed by a counter **38**. In the illustrated embodiment wherein n=5, field strength current source **24***a* is potentially capable of sourcing thirty-two distinct reference current levels. We propose that the initial, minimum reference current level be selected so as to be less than the current carrying capacity of the mirror transistor **34** when the shunt circuit **18***a* first begins to shunt excess induced current through reference transistor **32**; that the maximum reference current level be selected so as to be greater than the current carrying capacity of the mirror transistor **34** when the shunt circuit **18***a* is shunting a maximum anticipated amount of excess induced current; and that the intermediate reference current levels be distributed relatively evenly between the minimum and maximum levels. Of course, alternate schemes may be practicable, and, perhaps, desirable depending on system requirements.

Within control **26***a*, a conventional analog-to-digital converter ("ADC") **40**, having its input connected to a sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**. In one embodiment, ADC **40** may comprise a comparator circuit adapted to switch from a logic_0 state to a logic_1 when sufficient current is sourced by field strength current source **24***a* to raise the voltage on sensing node **36** above a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system. Sufficient current may be characterized as that current sourced by the field strength current source **24***a* or sunk by mirror transistor **34** such that the voltage on sensing node **36** is altered substantially above or below a predetermined reference voltage threshold, v_{th}. In the exemplary case of a simple CMOS inverter, v_{th} is, in its simplest form, one-half of the supply voltage (VDD/2). Those skilled in the art will appreciate that v_{th} may by appropriately modified by altering the widths and lengths of the devices of which the inverter is comprised. In the exemplary case a multi-bit ADC, v_{th} may be established by design depending on the system requirements and furthermore, may be programmable by the system.

In the illustrated embodiment, a latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. If the captured state is logic_0, the clock/control circuit **44** will change counter **38** to change the reference current being sourced by field strength current source **24***a*; otherwise clock/control circuit **44** will, at least temporarily, cease operation. However, notwithstanding, the digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

By way of example, we have illustrated in FIG. **4** one possible general operational flow of our field strength detector **20***a*. Upon activation, counter **38** is set to its initial digital field-strength value (step **48**), thereby enabling field strength current source **24***a* to initiate reference current sourcing at the selected level. After an appropriate settling time, the field strength reference voltage, v_R, developed on sensing node **36** and digitized by ADC **40** is captured in latch **42** (step **50**). If the captured field strength reference voltage, v_R, is less than (or equal to) the predetermined reference threshold voltage, v_{th}, clock/control **44** will change counter **38** (step **54**). This process will repeat, changing the reference current sourced by field strength current source **24***a* until the captured field strength reference voltage, v_R, is greater than the predetermined reference threshold voltage, v_{th}, (at step **52**), at which time the process will stop (step **56**). As illustrated, this sweep process can be selectively reactivated as required, beginning each time at either the initial field-strength value or some other selected value within the possible range of values as desired.

The graph illustrated in FIG. **5** depicts several plots of the voltage developed on sensing node **36** as the field strength detector circuit **20***a* sweeps the value of counter **38** according to the flow illustrated in FIG. **4**. As an example, note that the curve labeled "A" in FIG. **5** begins at a logic_0 value when the value of counter **38** is at a minimum value such as "1" as an exemplary value. Subsequent loops though the sweep loop gradually increase the field strength reference voltage on sensing node **36** until counter **38** reaches a value of "4" as an example. At this point, the "A" plot in FIG. **5** switches from a logic_0 value to a logic_1 value, indicating that the field strength reference voltage, v_R, on sensing node **36** has exceeded the predetermined reference threshold voltage, v_{th}. Other curves labeled "B" through "D" depict incremental increases of reference currents, i_R, flowing through reference device **32**, resulting in correspondingly higher mirrored currents flowing through mirror device **34**. This incrementally higher mirror current requires field strength current source **24** to source a higher current level which in turn corresponds to higher values in counter **38**. Thus, it is clear that our invention is adapted to effectively and efficiently develop a digital representation of the current flowing through sensing node **36** that is suitable for any appropriate use.

One such use, as discussed earlier, of our field strength detector **20** is to cooperate with tuner **16** in controlling the operating characteristics of the tank circuit **14**. FIG. **6** illustrates one possible embodiment where receiver circuit **10***a* uses a field strength detector **20***b* specially adapted to share with tuner **16***a* the control of the tank circuit **14**. In our Related References we have disclosed methods, and related apparatus, for dynamically tuning, via tuner **16***a*, the tank circuit **14** so as to dynamically shift the f_R of the tank circuit **14** to better match the f_C of the received RF signal at antenna **12**. By way of example, we have shown in FIG. **6** how the embodiment shown in FIG. 3 of our Related Patent may be easily modified by adding to tuner **16***a* a multiplexer **58** to facilitate shared access to the tuner control apparatus. Shown in FIG. **7** is the operational flow (similar to that illustrated in FIG. 4 in our Related Patent) of our new field strength detector **20***b* upon assuming control of tank circuit **14**.

In context of this particular use, once tuner **16***a* has completed its initial operating sequences as fully described in our Related Patent, and our field strength detector **20***b* has performed an initial sweep (as described above and illustrated in FIG. **4**) and saved in a differentiator **60** a base-line field-strength value developed in counter **38**, clock/control **44** commands multiplexer **58** to transfer control of the tank circuit **16***a* to field strength detector **20***b* (all comprising step **62** in FIG. **7**). Upon completing a second current sweep, differentiator **60** will save the then-current field-strength value developed in the counter **38** (step **64**). Thereafter, differentiator **60** will determine the polarity of the change of the previously saved field-strength value with respect to the then-current field-strength value developed in counter **38** (step **66**). If the polarity is negative (step **68**), indicating that the current field-strength value is lower than the previously-saved field-strength value, differentiator **60** will assert a change direction signal; otherwise, differentiator **60** will negate the change direction signal (step **70**). In response, the shared components in tuner **16***a* downstream of the multiplexer **58** will change the tuning characteristics of tank circuit **14** (step **72**) (as fully described in our Related References). Now, looping back (to step **64**), the resulting change of field strength, as quantized is the digital field-strength value developed in counter **38** during the next sweep (step **64**), will be detected and, if higher, will result in a further shift in the f_R of the tank circuit **14** in the selected direction or, if lower, will result in a change of direction (step **70**). Accordingly, over a number of such 'seek' cycles, our invention will selectively allow the receiver **10***a* to maximize received field strength even if, as a result of unusual factors, the f_R of the tank circuit **14** may not be precisely matched to the f_C of the received RF signal, i.e., the reactance of the antenna is closely matched with the reactance of the tank circuit, thus achieving maximum power transfer. In an alternative embodiment, it would be unnecessary for tuner **16***a* to perform an initial operating sequence as fully described in our Related Patent. Rather, field strength detector **20***b* may be used exclusively to perform both the initial tuning of the receiver circuit **10***a* as well as the subsequent field strength detection. Note that the source impedance of antenna **12** and load impedance of tank circuit **14** may be represented alternatively in schematic form as in FIG. **8**, wherein antenna **12** is represented as equivalent source resistance R_S **74** and equivalent source reactance X_S **76**, and tank circuit **14** is represented as equivalent load resistance R_L **78** and equivalent, variable load reactance X_L **80**.

In FIG. **9**, we have illustrated an alternate embodiment of our field strength detector illustrated in FIG. **3**. Here, as before, shunt circuit **18***b* is used to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. Also, as before, the current reference **22** is implemented as a current mirror circuit **22***b* connected in series with shunt circuit **18***b* between nodes **28** and **30**. However, in this embodiment, the field strength current source comprises a resistive component **84** adapted to function as a static resistive pull-up device. Many possible implementations exist besides a basic resistor, such as a long channel length transistor, and those skilled in the art will appreciate the various implementations that are available to accomplish analogous functionality. The field strength voltage reference v_R developed on sensing node **36** will be drawn to a state near the supply voltage when the mirrored current flowing though transistor **34** is relatively small, e.g. close to zero amps, indicating a weak field strength. As the field strength increases, the current flowing through mirror transistor **34** will increase, and the field strength voltage reference v_R developed on sensing node **36** will drop proportionally to the mirrored current flowing through mirror transistor **34** as i_R/N. ADC **40**, having its input connected to sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**, as described previously.

In this alternate embodiment, latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. As disclosed earlier, the ADC **40** may comprise a comparator circuit. In this instance, ADC **40** is adapted to switch from a logic_1 state to a logic_0 when sufficient current is sunk by mirror transistor **34** to lower the voltage on sensing node **36** below a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system.

Comparator **82** subsequently compares the captured output state held in latch **42** with a value held in counter **38** that is selectively controlled by clock/control circuit **44**. In response to the output generated by comparator **82**, clock/control circuit **44** may selectively change the value held in counter **38** to be one of a higher value or a lower value, depending on the algorithm employed. Depending upon the implementation of counter **38** and comparator **82**, clock/control circuit **44** may also selectively reset the value of counter **38** or comparator **82** or both. The digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

In FIG. **10**, we have illustrated another alternate embodiment of our field strength detector illustrated in FIG. **3**. Here, as before, shunt circuit **18***c* is used to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. In this embodiment, the current reference **22** is implemented as a resistive component **86** that functions as a static pull-down device. Many possible implementations exist besides a basic resistor, such as a long channel length transistor and those skilled in the art will appreciate the various implementations that are available to accomplish analogous functionality. The field strength voltage reference v_R developed on sensing node **36** will be drawn to a state near the ground node when the current flowing though shunt circuit **18***c* is relatively small, e.g., close to zero amps, indicating a weak field strength. As the field strength increase, the current flowing through shunt circuit **18***c* will increase, and the field strength voltage reference v_R developed on sensing node **36** will rise proportionally to the current flowing through shunt circuit **18***c*. ADC **40**, having its input connected to a sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**, as described previously.

In this alternate embodiment, latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. As disclosed earlier, the ADC **40** may comprise a comparator circuit. In this instance, ADC **40** is adapted to switch from a logic_0 state to a logic_1 when sufficient current is sourced by shunt circuit **18***c* to raise the voltage on sensing node **36** above a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system.

Comparator **82** subsequently compares the captured output state held in latch **42** with a value held in counter **38** that is selectively controlled by clock/control circuit **44**. In response to the output generated by comparator **82**, clock/control circuit **44** may selectively change the value held in counter **38** to be one of a higher value or a lower value, depending on the algorithm employed. Depending upon the implementation of counter **38** and comparator **82**, clock/control circuit **44** may also selectively reset the value of counter **38** or comparator **82** or both. The digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

In another embodiment, our invention may be adapted to sense the environment to which a tag is exposed, as well as sensing changes to that same environment. As disclosed in our Related References, the auto-tuning capability of tuner **16** acting in conjunction with tank circuit **14** detects antenna impedance changes. These impedance changes may be a function of environmental factors such as proximity to interfering substances, e.g., metals or liquids, as well as a function of a reader or receiver antenna orientation. Likewise, as disclosed herein, our field strength (i.e., received power) detector **20** may be used to detect changes in received power (i.e., field strength) as a function of, for example, power emitted by the reader, distance between tag and reader, physical characteristics of materials or elements in the immediate vicinity of the tag and reader, or the like.

Sensing the environment or, at least, changes to the environment is accomplished using one or both of these capabilities.

As an example, the tag **88** of FIG. **11**, contains both a source tag antenna **12** (not shown, but see, e.g., FIG. **6**) and a corresponding load chip tank circuit **14** (not shown, but see, e.g., FIG. **6**). Each contains both resistive and reactive elements as discussed previously (see, e.g., FIG. **8**). A tag **88** containing such a tank circuit **14** mounted on a metallic surface will exhibit antenna impedance that is dramatically different than the same tag **88** in free space or mounted on a container of liquid. Table 1 displays exemplary values for impedance variations in both antenna source resistance **74** as well as antenna source reactance **76** as a function of frequency as well as environmental effects at an exemplary frequency:

TABLE 1

Antenna Impedance Variations			
In Free Air	860 MHz	910 MHz	960 MHz
R_S	1.9	2.5	3.7
X_S	124	136	149
@910 MHz	Free Air	On Water	On Metal
R_S	2.5	26	1.9
X_S	136	136	27

The tuner circuit **16** of our invention as disclosed in the Related References automatically adjusts the load impendence by adjusting load reactance **80** (see, e.g., FIG. **8**) to match source antenna impedance represented by source resistance **74** (see, e.g., FIG. **8**) and source reactance **76** (see, e.g., FIG. **8**). As previously disclosed, matching of the chip load impedance and antenna source impedance can be performed automatically in order to achieve maximum power transfer between the antenna and the chip. My invention as disclosed in the Related References contained a digital shift register **90** for selectively changing the value of the load reactive component, in the present case a variable capacitor, until power transfer is maximized. This digital value of the matched impendence may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, tag **88** may contain a calibrated look-up-table within the clock/control circuit **44** which may be accessed to determine the relevant environmental information. Likewise, a RFID reader **92** may issue commands (see transaction **1** in FIG. **11**) to retrieve (see transaction **2** in FIG. **11**) the values contained in digital shift register **90** via conventional means, and use that retrieved information to evaluate the environment to which tag **88** is exposed. The evaluation could be as simple as referencing fixed data in memory that has already been stored and calibrated, or as complex as a software application running on the reader or its connected systems for performing interpretive evaluations.

Likewise, consider a tag **88** containing our field strength (i.e., received power) detector **20** (not shown, but, e.g., see FIG. **6**) wherein the method of operation of the system containing the tag **88** calls for our field strength detector **20** to selectively perform its sweep function and developing the quantized digital representation of the current via the method discussed earlier. As illustrated in FIG. **11**, counter **38** will contain the digital representation developed by our field strength detector **20** of the RF signal induced current, and may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, reader **92** may issue a command to the tag **88** (see transaction **1** in FIG. **11**) to activate tuner **16** and/or detector **20** and, subsequent to the respective operations of tuner **16** and/or detector **20**, receive (see transaction **2** in FIG. **11**) the digital representations of either the matched impedance or the maximum current developed during those operations. Once again, this digital value of the field strength stored in the counter **38** may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, tag **88** may contain a calibrated look-up-table within the clock and control block **44** which may be accessed to determine the relevant environmental information. Likewise, a RFID reader may issue commands to retrieve the values contained in digital shift register **90**, and use that retrieved information to evaluate the environment to which tag **88** is exposed. The evaluation could be as simple as referencing fixed data in memory that has already been stored and calibrated, or as complex as a software application running on the reader or its connected systems for performing interpretive evaluations. Thus, the combining of the technologies enables a user to sense the environment to which a tag **88** is exposed as well as sense changes to that same environment.

Thus, it is apparent that we have provided an effective and efficient method and apparatus for quantizing the received RF field strength as a function of induced current. We have developed this field quantization in a form and manner that is suitable for selectively varying the impedance of the tank circuit to maximize received power, especially during normal system operation. Those skilled in the art will recognize that modifications and variations can be made without departing from the spirit of our invention. Therefore, we intend that our invention encompass all such variations and modifications as fall within the scope of the appended claims.

What is claimed is:

1. A radio frequency (RF) circuit comprises:

an antenna operably coupled to receive an RF signal;

a power harvesting circuit operable to generate a first power source from the RF signal;

a tank circuit coupled to the antenna, wherein the tank circuit includes a selectively variable impedance; and

a tuning circuit operable to dynamically vary the selectively variable impedance of the tank circuit based on resonance of the RF circuit and frequency of the RF signal to substantially align the resonance of the RF circuit with the frequency of the RF signal, wherein, when the resonance of the RF circuit is substantially aligned with the frequency of the RF signal, the power harvesting circuit generates a second power source from the RF signal, wherein the second power source is greater than the first power source.

2. The RF circuit of claim **1** further comprises:

a processing module operable to generate a digital value representative of dynamic variance of the selectively variable impedance of the tank circuit;

memory operable coupled to the processing module; and

a transmitter section operable to transmit an outbound RF signal to a reader, wherein the outbound RF signal includes the digital value.

3. The RF circuit of claim **2** further comprises:

the antenna operable to receive a second RF signal, wherein the second RF signal has an adjusted transmit power with respect to the RF signal based on an interpretation of the digital value such that the second power source is at least one of a desired voltage level and a desired current level.

4. The RF circuit of claim **1**, wherein the tank circuit comprises:

an inductor; and

a variable capacitor coupled to the inductor, wherein the tuning circuit is operable to adjust capacitance of the variable capacitor such that a resonant frequency of the tank circuit substantially matches a frequency of the RF signal.

5. The RF circuit of claim **1**, wherein the power harvesting circuit comprises:

a regulator coupled to the tank circuit, wherein a current is induced in the tank circuit from the received RF signal, wherein the regulator is operable to extract a portion of the induced current to provide direct current (DC) operating power to the RF circuit.

6. The RF circuit of claim **1** further comprises:

a sensing circuit that includes:

the tank circuit having the selectively variable impedance;

the tuning circuit operable to dynamically vary the impedance of the tank circuit, and to develop a first quantized value representative of the impedance of the tank circuit; and

a detector circuit operable to develop a second quantized value as a function of a field strength of a received RF signal; and

memory, wherein the memory stores the first and second quantized values; and

a control circuit operable selectively to retrieve the first and second quantized values from the memory, wherein the retrieved first and second quantized values are used to sense changes to an environment to which the RF circuit is exposed.

7. The RF circuit of claim **6**, wherein the environment includes one or more of:

free space;

air;

liquids; and

metals.

8. The RF circuit of claim **1**, wherein the selectively variable impedance is set to an initial value.

(57) **ABSTRACT**

A cloaking device includes cloaking region boundary planes oriented non-planar to each other, each of the cloaking region boundary planes having an outward facing mirror surface and an inward facing opaque surface. The cloaking device includes a cloaking region bounded at least partially by the inward facing opaque surfaces of the cloaking region boundary planes. Half mirrors are spaced apart from and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart from and generally parallel to each outward facing mirror surface. Light from an object on an object-side of the cloaking device is directed around an article within the cloaking region and forms an image on an image-side of the cloaking device such the article appears transparent to an observer looking towards the object.

APPARATUSES AND METHODS FOR MAKING AN OBJECT APPEAR TRANSPARENT

RELATED APPLICATION

This application claims the benefit of U.S. Provisional Patent Application Ser. No. 62/291,920 filed Feb. 5, 2016, the entirety of which is incorporated herein by reference.

TECHNICAL FIELD

The present specification generally relates to apparatuses and methods for making an object appear transparent and, more specifically, to cloaking devices for pillars of vehicles and methods for making pillars of vehicles appear transparent.

BACKGROUND

Studies on cloaking devices that appear to make a pillar of a vehicle transparent have been published. Such studies disclose the use of metamaterials or the use of video cameras in combination with a display screen to allow an occupant of a vehicle to ostensibly "see" though the vehicle pillar, thereby reducing blind spots in the vehicle. However, metamaterials and video technology use complicated material designs and equipment.

Accordingly, a need exists for alternative devices that appear to make a pillar of a vehicle transparent.

SUMMARY

In one embodiment, a cloaking device includes cloaking region (CR) boundary planes oriented non-planar to each other and each of the CR boundary planes has an outward facing mirror surface and an inward facing opaque surface. The cloaking device includes a CR at least partially bounded by the inward facing opaque surfaces of the CR boundary planes. The cloaking device includes half mirrors spaced apart from and generally parallel to the outward facing mirror surfaces such that a half mirror is spaced apart from and generally parallel to each outward facing mirror surface. An article positioned within the CR is not visible outside of the CR and light reflected from an object on one side of the cloaking device is redirected around the CR and the article positioned within the CR, and forms an image of the object on another side of the cloaking device.

According to another embodiment, a cloaking device for cloaking an article of a vehicle includes a cloaking assembly with an object-side, an image-side and at least two CR boundary planes positioned at least partially between the object-side and the image-side. The at least two CR boundary planes are positioned non-planar to each other and each of the at least two CR boundary planes have an outward facing mirror surface and an inward facing opaque surface. A CR is bounded by the inward facing opaque surfaces of the at least two CR boundary planes and a vehicle article positioned within the CR is not visible from outside the CR. The cloaking assembly has at least two half mirrors positioned at least partially between the object-side and the image-side. Each of the at least two half mirrors is spaced apart from and generally parallel to one of the outward facing mirror surfaces such that a half mirror is spaced apart from and generally parallel to each outward facing mirror surface. Light from an object located on the object-side of the cloaking assembly, and obscured by the vehicle article

positioned within the CR is redirected around the CR, and forms an image of the object on the image-side of the cloaking assembly such that the vehicle article appears transparent to an observer looking in a direction towards the object.

In embodiments, the cloaking assembly has four CR boundary planes and four half mirrors. The four CR boundary planes are oriented generally orthogonal to each other, the CR is bounded by the four CR boundary planes, and each of the half mirrors are spaced apart and generally parallel to one of the outward facing mirror surfaces such that a half mirror is spaced apart and generally parallel to each outward facing mirror surface. Each of the half mirrors may be selected from a p-polarization half mirror or an s-polarization half mirror. Light reflected from the object located on the object-side of the cloaking assembly passes through the cloaking assembly by reflecting off of a first outward facing mirror surface, a first half mirror oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror. Light that passes through the cloaking assembly forms an image of the object on the image-side of the cloaking assembly.

In embodiments, the cloaking device with the cloaking assembly has an end surface oriented non-planar to a half mirror. Light from an item located adjacent to the end surface passes through the cloaking assembly and forms an image of the item on the image side of the cloaking assembly.

These and additional features provided by the embodiments described herein will be more fully understood in view of the following detailed description in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

The embodiments set forth in the drawings are illustrative and exemplary in nature and not intended to limit the subject matter defined by the claims. The following detailed description of the illustrative embodiments can be understood when read in conjunction with the following drawings, where like structure is indicated with like reference numerals and in which:

FIG. **1** schematically depicts a top view of a cloaking device according to one or more embodiments described and illustrated herein;

FIG. **2** schematically depicts top isolated views of four cloaking device components of the cloaking device of FIG. **1** according to one or more embodiments described and illustrated herein;

FIG. **3** schematically depicts a top perspective view of the cloaking device of FIG. **1** with a first object on one side of the cloaking device and a second object within a cloaking region (CR) of the cloaking device;

FIG. **4** schematically depicts a side view of the cloaking device of FIG. **3** with the first object on one side of the cloaking device and the second object within the CR of the cloaking device;

FIG. **5** schematically depicts a top view of a cloaking device according to one or more embodiments described and illustrated herein;

FIG. **6** schematically depicts a top perspective view of the cloaking device of FIG. **5** with a first object on one side of the cloaking device and a second object and a third object within a CR of the cloaking device;

FIG. **7** schematically depicts a side view of the cloaking device of FIG. **6** with the first object on one side of the cloaking device and the second object and the third object within the CR of the cloaking device;

FIG. **8** schematically depicts a top isolated view of two cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **9** schematically depicts a top view of a cloaking device with four cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **10** schematically depicts a side view of the cloaking device shown in FIG. **9**;

FIG. **11** schematically depicts a top isolated view of two cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **12** schematically depicts a top view of a cloaking device with four cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **13** schematically depicts a side view of the cloaking device of FIG. **12**;

FIG. **14** schematically depicts a top isolated view of two cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **15** schematically depicts a top view of four cloaking device components according to one or more embodiments described and illustrated herein;

FIG. **16** schematically depicts a side view of the cloaking device of FIG. **15**;

FIG. **17** schematically depicts a side view of a cloaking device cloaking an A-pillar of a vehicle according to one or more embodiments described and illustrated herein;

FIG. **18** schematically depicts a top view of a cloaking device according to one or more embodiments described and illustrated herein; and

FIG. **19** schematically depicts a top view of a cloaking device with four cloaking device components according to one or more embodiments described and illustrated herein.

DETAILED DESCRIPTION

A cloaking device is provided. The cloaking device may have an object-side, an image-side and a cloaking region (CR) boundary plane having an outward facing mirror surface and an inward facing opaque surface. A CR is at least partially bounded by the inward facing opaque surface of the CR boundary plane and a half mirror is spaced apart from and generally parallel to the outward facing mirror surface. The half mirror may be a p-polarization half mirror or an s-polarization half mirror. In embodiments, an article, e.g. an A-pillar of a vehicle, a B-pillar of a vehicle or a C-pillar of a vehicle, is positioned within the CR and light from an object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the article and forms the image of the object on the image-side of the cloaking device such that the article appears transparent. Various embodiments of cloaking devices and methods for using the same will be described in further detail herein with specific reference to the appended drawings.

FIG. **1** generally depicts one embodiment of a cloaking device. The cloaking device includes a cloaking region (CR) that is at least partially bounded by at least two CR boundary planes that are non-planar to each other. Each of the two CR boundary planes has an outward facing mirror surface and an inward facing opaque surface. Spaced apart from and oriented generally parallel to each of the CR boundary planes is a half mirror (e.g., a polarizing half mirror) that allows p-polarized light to pass through and s-polarized light to be reflected or, alternatively, allows s-polarized light to pass through and p-polarized light to be reflected. Referring to the coordinate system in the figure, portions of a target object are located directly behind the CR in the +Y direction (obscured portions of the object which are otherwise not visible through the CR) and portions of the target object are located outside or beyond the CR in the +Y direction (visible portions of the object). Light rays (light) from the obscured portions of the target object travel in the −Y direction and are incident on a first outward facing mirror surface. The first outward facing mirror surface reflects the incident light from the obscured portions of the target object in the +X direction to a first half mirror that is spaced apart from and oriented generally parallel to the first outward facing mirror surface. One mode of polarized light (e.g., p-polarized light) from the light reflected from the first outward facing mirror surface passes through the first half mirror (continues traveling in the +X direction), while another mode of polarized light (e.g. s-polarized light) is reflected by the first half mirror in the −Y direction. The polarized light reflected in the −Y direction by the first half mirror is reflected into the −X direction by a second half mirror. The polarized light reflected into the −X direction by the second half mirror is reflected in the −Y direction by a second outward facing mirror surface that is spaced apart from and oriented generally parallel to the second half mirror. An observer looking at the cloaking device in the +Y direction will see the reflection of the polarized light by the second outward facing mirror surface, i.e. polarized light originating from light from obscured portions of the target object will be visible to a human eye located on an opposite side of the CR from the obscured portions of the target object. Also, light reflected from an article positioned within the CR (i.e., the cloaked article) is not transmitted through the inward facing opaque surfaces and is not seen by the observer looking at the cloaking device in the +Y direction. That is, the cloaking device effectively redirects light from the obscured portions of the target object around the CR such that the light from the target object appears to pass through the cloaked article giving the visual impression that the cloaked article is not present. Light from the visible portions of the target object travels in the −Y direction and is incident on the first half mirror. One mode of the incident light (e.g., s-polarized light) is reflected in the +X direction by the first half mirror and another mode of the incident light (e.g. p-polarized light) is transmitted through the first half mirror and continues traveling in the −Y direction. The transmitted polarized light traveling in the −Y direction reaches the second half mirror and is transmitted through the second half mirror. An observer looking at the cloaking device in the +Y direction will see the transmitted polarized light traveling in the −Y direction, i.e. polarized light originating from light from visible portions of the target object will be visible to a human eye located on an opposite side of the cloaking device from the visible portions of the target object. Accordingly, an individual will see the entire target object, both obscured portions and visible portions, that is located on the opposite side of the CR (and thus on the opposite side of a cloaked article) giving the visual impression that the cloaked article is transparent.

Referring now to FIGS. **1-2**, embodiments of a cloaking device include a cloaking assembly **10** with four CR boundary planes **118**, **128**, **138**, **148**. The CR boundary planes **118**, **128**, **138**, **148** located adjacent to each other are non-planar to each other. In embodiments, opposing CR boundary planes **118**, **148** and **128**, **138** may be oriented parallel to each other and adjacent CR boundary planes **118**, **128**, **138**,

148 may be oriented orthogonal to adjacent CR boundary planes, e.g. CR boundary plane **118** is oriented orthogonal to adjacent CR boundary planes **138**, **128**, CR boundary plane **128** is oriented orthogonal to adjacent CR boundary planes **118**, **148**, etc. Each of the four CR boundary planes has an outward facing mirror surface **118***a*, **128***a*, **138***a*, **148***a*, respectively, and an inward facing opaque surface **118***b*, **128***b*, **138***b*, **148***b*, respectively. The outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, can be made from omni-directional photonic crystals or mirrors such that approximately 100% (+/−10%) of light incident on the outward facing mirror surfaces is reflected from the outward facing mirror surfaces. Accordingly, the term "mirror surface" used herein refers to a surface that reflects approximately 100% (+/−10%) of all modes of light (e.g. s-polarized light and p-polarized light) incident on the mirror surface. In embodiments, the CR boundary planes **118**, **128**, **138**, **148** form a CR **200** bound at least partly by the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*. The four CR boundary planes **118**, **128**, **138** **148**, have a height 'h' (FIG. **4**) in the Z direction of the coordinate axes in the figures and light reflected or transmitted within the CR **200** does not pass through the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*. Accordingly, an article (e.g., a cloaked article) located within the CR **200** is not visible to an observer viewing the cloaking assembly **10** in the +Y direction.

Still referring to FIGS. **1** and **2**, spaced apart from and oriented generally parallel (within +/−2°) to the four CR boundary planes **118**, **128**, **138** **148**, are half mirrors **115**, **125**, **135**, **145**, respectively. The half-mirrors **115**, **125**, **135**, **145** reflect a specific mode of visible light Specifically, each of the half mirrors **115**, **125**, **135**, **145** can be an s-polarizer half mirror or a p-polarizer half mirror. The half mirrors **115**, **125**, **135**, **145** can be in the form of a diffraction grating or thin film polarizer that reflects the s-mode of visible light and allows the p-mode of visible light to pass through (a p-polarization diffraction grating or thin film), or in the alternative, reflects the p-mode of visible light and allows the s-mode of the visible light to pass through (an s-polarization diffraction grating or thin film). It should be appreciated that the half mirrors **115**, **125** are both s-polarizer half mirrors or p-polarizer half mirrors and the half mirrors **135**, **145** are both s-polarizer half mirrors or p-polarizer half mirrors, i.e. the half mirrors **115**, **125** may be s-polarizer mirrors and the half mirrors **135**, **145** may be p-polarizer half mirrors; the half mirrors **115**, **125** may be p-polarizer mirrors and the half mirrors **135**, **145** may be s-polarizer half mirrors; or all of the half mirrors **115**, **125**, **135**, **145** may be s-polarizer half mirrors or p-polarizer half mirrors.

The four CR boundary planes **118**, **128**. **138** **148**, and the corresponding half mirrors **115**, **125**, **135**, **145**, may be part of four cloaking assembly components **110**, **120**, **130**, **140**, respectively. Each of cloaking assembly components **110**, **120**, **130**, **140** has an outward facing surface **112**, **122**, **132**, **142**, respectively, an inward facing surface **114**, **124**, **134**, **144**, respectively, an outer end surface **116**, **126**, **136**, **146**, respectively, and an inner side surface defined by the inward facing opaque surface **118***b*, **128***b*, **138***b*, **148***b*, respectively. The outward facing surfaces **112**, **132** form an object-side **102** of the cloaking device and the outward facing surfaces **122**, **142** form an image-side **104** of the cloaking device. One or more optical filters **125***a*, **125***b* may be positioned on or adjacent to the outward facing surface **122** and one or more optical filters **145***a*, **145***b* may be positioned on or adjacent to the outward facing surface **142**. The optical filter **125***a* is positioned to the right (+X direction) of the half-mirror **125**, the optical filter **125***b* is positioned to the left (−X direction) of the half-mirror **125**, the optical filter **145***a* is positioned to the left (−X direction) of the half-mirror **145**, and the optical filter **145***b* is positioned to the right (+X direction) of the half-mirror **145**. The one or more optical filters **125***a*, **125***b*, **145***a*, **145***b* may be quarter-wave plates that convert linearly polarized light into circularly polarized light, or in the alternative, the one or more optical filters **125***a*, **125***b*, **145***a*, **145***b* may be a quarter-wave plate and a linear polarizer that convert linearly polarized light of one mode, e.g., s-mode or p-mode, into circularly polarized light, and then convert the circularly polarized light into a different linearly polarized mode, e.g., p-mode or s-mode, respectively.

The CR boundary planes **118**, **138** are oriented at an angle θ_1 relative to the outward facing surfaces **112**, **132**, respectively, and the CR boundary planes **128**, **148** are oriented at an angle β_1 relative to the outward facing surfaces **122**, **142**, respectively. In embodiments, the angle θ_1 is equal to the angle β_1. In other embodiments, the angle θ_1 is not equal to the angle β_1. The half mirrors **115**, **135** are oriented at an angle θ_2 relative to the outward facing surfaces **112**, **132**, respectively, and the half mirrors **125**, **145** are oriented at an angle β_2 relative to the outward facing surfaces **122**, **142**, respectively. In embodiments, the angle θ_2 is equal to the angle β_2. In other embodiments, the angle θ_2 is not equal to the angle β_2. In embodiments, the angle θ_1 is equal to the angle θ_2 and the angle β_1 is equal to the angle β_2. For example, θ_1 and θ_2 can be generally equal to 45° (+/−1°), and β_1 and β_2 can be generally equal to 45° (+/−10).

The four cloaking assembly components **110**, **120**, **130**, **140** are transparent to incident light (both polarized and unpolarized) except for the half mirrors **115**, **125**, **135**, **145**, the outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, the inward facing opaque surfaces **118***b*, **128***b*, **138***b*, **148***b*, and optionally the outer end surfaces **116**, **126**, **136**, **146**. The four cloaking assembly components **110**, **120**, **130**, **140** can be made from any suitable transparent material, for example a transparent glass or a transparent plastic. In the alternative, the four cloaking assembly components **110**, **120**, **130**, **140** can be a structure, e.g. a frame, that holds the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**. The frame may be a plurality of transparent glass or transparent plastic panes that hold the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**. In embodiments, transparent glass or transparent plastic panes form the outward facing surfaces **112**, **122**, **132**, **142**, inward facing surfaces **114**, **124**, **134**, **144**, and outer end surfaces **116**, **126**, **136**, **146**, and hold the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** in a desired orientation relative to each other with air or another gas present between the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145**.

The outer end surfaces **116**, **126**, **136**, **146** may be transparent, have an absorber layer disposed thereon or be a half-mirror. In embodiments, the outer end surfaces **116**, **126**, **136**, **146** are transparent. In other embodiments, the outer end surfaces **116**, **126**, **136**, **146** have an absorber layer disposed thereon that absorbs incident light from within the four cloaking assembly components **110**, **120**, **130**, **140**, and/or from outside the four cloaking assembly components

110, **120**, **130**, **140**. The absorber layer may be made from any suitable material that absorbs approximately 90% (+/−10%) of incident light, illustratively including dark colored surfaces made of glass, polymers, metals, ceramics, composites, etc. In other embodiments, the outer end surfaces **116**, **126**, **136**, **146** are half-mirrors such that one mode of incident light is reflected (e.g., s-polarized light or p-polarized light) and another mode of incident light is transmitted through the half mirror (e.g., p-polarized light or s-polarized light, respectively). In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146** is transparent and one or more of the outer end surfaces **116**, **126**, **136**, **146** has an absorber layer disposed thereon. In other embodiments, one or more outer end surfaces **116**, **126**, **136**, **146** is transparent and one or more of the outer end surfaces **116**, **126**, **136**, **146** is a half mirror. In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146** has an absorber layer disposed thereon and one or more of the outer end surfaces **116**, **126**, **136**, **146** is a half mirror. In other embodiments, one or more of the outer end surfaces **116**, **126**, **136**, **146** is transparent, one or more of the outer end surfaces **116**, **126**, **136**, **146** has an absorber layer disposed thereon, and one or more of the outer end surfaces **116**, **126**, **136**, **146** is a half mirror.

While FIGS. **1**-**2** illustrate four cloaking assembly components **110**, **120**, **130**, **140**, it should be appreciated that the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** can be contained within any number of cloaking assembly components. For example, in embodiments, the cloaking assembly components **110** and **120** may be a single cloaking assembly component with no inward facing surface **114**, **124**, between the outward facing surfaces **112**, **122**, and the cloaking assembly components **130** and **140** may be a single cloaking assembly component with no inward facing surface **134**, **144**, between the outward facing surfaces **132**, **142**. In other embodiments, the cloaking assembly components **110** and **130** may be a single cloaking assembly component and the two cloaking assembly components **120** and **140** can be a single cloaking assembly component. In other embodiments, three of the four cloaking assembly components **110**, **120**, **130**, **140** may be a single cloaking assembly component assembled with a remaining one of the cloaking assembly components **110**, **120**, **130**, **140**. For example, the three cloaking assembly components **110**, **120**, **130** may be a single cloaking assembly component assembled with the remaining cloaking assembly component **140**. In other embodiments, the four cloaking assembly components **110**, **120**, **130**, **140** may be a single cloaking assembly component.

Still referring to FIGS. **1**-**2**, light 'lo' is reflected from an object 'O' (e.g., a target object) located on the object-side **102** of the cloaking device, travels in the −Y direction, and is incident on and transmitted through the outward facing surfaces **112**, **132**. The light lo reflected from the obscured portions of the object 'O' located directly behind the CR in the +Y direction is reflected by the outward facing mirror surfaces **118***a*, **138***a* in the +X and −X directions, respectively. The light lo reflected in the +X and −X directions is incident on the half mirrors **115**, **135** respectively. As illustrated in FIG. **1**, the half mirrors **115**, **135** are p-polarization half mirrors that reflect the s-mode (ls) of the light lo and allow the p-mode (lp) of the light lo to pass through. The s-polarized light ls reflected from the half mirrors **115**, **135** in the −Y direction is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** are also p-polarization mirrors that reflect the s-polarized light ls traveling in the −Y direction into the −X and +X directions, respectively. The s-polarized light ls reflected in the −X and +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively, and the outward facing mirror surfaces **128***a*, **148***a* reflect the incident s-polarized light ls into the −Y direction. The s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a*, forms an image of the obscured portion of the target object located directly above the CR **200** in the +Y direction that is visible to an observer viewing the image-side **104** of the cloaking assembly **10**. In embodiments, the optical filter **125***b*, the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be positioned on or adjacent to the outward facing surfaces **122**, **142**, respectively, as described above, and may convert the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a*, into circularly polarized light or p-polarized light. For example, the optical filter **125***b* the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be quarter wave plates that convert the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) before forming the image of the obscured portion of the target object 'O' located directly above the CR **200** in the +Y direction. In the alternative, the optical filter **125***b*, the optical filter **145***b*, or both optical filters **125***b*, **145***b* may be a quarter-wave plate and a linear polarizer that converts the s-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) and then converts the circularly polarized light into p-polarized light before forming the image of the obscured portion of the target object 'O' located directly above the CR **200** in the +Y direction.

Light lo reflected from the visible portions of the target object 'O' not located directly behind the CR in the +Y direction is incident on and transmitted through the outward facing surfaces **112**, **132**. The transmitted light lo is incident on the p-polarization half mirrors **115**, **135**. The half mirrors **115**, **135** reflect the s-mode is of the incident light lo in the +X and −X directions, respectively, and transmit the p-mode lp of the incident light lo in the −Y direction. The p-polarized light lp transmitted through the half mirrors **115**, **135** will be incident on and be transmitted through the p-polarization half mirrors **125**, **145**, respectively, in the −Y direction. The p-polarized light lp transmitted in the −Y direction by the half mirrors **125**, **145** forms an image of the visible portions of the target object O not located directly behind the CR **200** in the +Y direction that is visible to an observer viewing the cloaking assembly in the +Y direction. In embodiments, the optical filter **125***a*, the optical filter **145***a*, or both optical filters **125***a*, **145***a* may be positioned on or adjacent to the outward facing surfaces **122**, **142**, respectively, as described above, in order to convert the p-polarized light into circularly polarized light of s-polarized light. For example, the optical filter **125***a*, the optical filter **145***a* or both optical filters **125***a*, **145***a* may be quarter wave plates that convert the p-polarized light transmitted into the −Y direction by the half mirrors **125**, **145** into circularly polarized light (not shown) before forming the image of the visible portions of the target object 'O' not located behind above the CR **200** in the +Y direction. In the alternative, the optical filter **125***a*, the optical filter **145***a*, or both optical filters **125***a*, **145***a* may be a quarter-wave plate and a linear polarizer that convert the p-polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **148***a* into circularly polarized light (not shown) and then convert the circularly polarized light into s-polarized light before forming the image of the visible portions of the target object 'O' not located directly above the CR **200** in the +Y direction. Accordingly, an image 'I' of the entire target object 'O' (both the obscured portion and the visible portions) is visible to the observer viewing the image-side **104** of the cloaking assembly **10**. While half mirrors **115**, **125**, **135**, **145** are described herein as p-polarization half mirrors, it should be appreciated that half mirrors **115**, **125**, **135**, **145** can be s-polarization half mirrors and the reflected and transmitted portions of the reflected light lo discussed above will be reversed. However, the human eye cannot distinguish between s-polarized light, p-polarized light or circularly polarized light and the image 'I' of the entire object 'O' will be visible to the human eye when an observer is viewing the image-side **104** of the cloaking assembly **10**. Also, it should be appreciated that the one or more of optical filters **125***a*, **125***b*, **145***a*, **145***b* may be positioned on or adjacent to outward facing surfaces **122**, **142** as described above such that only p-polarized light forms the image 'I', only s-polarized light forms the image 'I', only circularly polarized light forms the image 'I', only p-polarized light and circularly polarized light form the image 'I' or only s-polarized light and circularly polarized light form the image 'I'. Such manipulation of the polarized light reflected into the −Y direction by the outward facing mirror surfaces **128***a*, **128***a* and the polarized light transmitted in the −Y direction by the half mirrors **125**, **145** may assist an observer wearing polarized sunglasses in viewing the image-side **104** of the cloaking assembly **10**. Particularly, the one or more optical filters **125***a*, **125***b*, **145***a*, **145***b* ensure that polarized sunglasses that block p-polarized light or s-polarized light do not prevent an observer wearing such polarized sunglasses from seeing the entire target object 'O' when viewing the image-side **104** of the cloaking assembly **10**.

Referring now to FIGS. **1**-**4**, a top perspective view and a side view of a cloaking device according to embodiments (as discussed with respect to FIGS. **1**-**2**) are shown in FIGS. **3**-**4**, respectively. Specifically, FIG. **3** is a top perspective view of an article in the form of a column 'C' within the CR **200** of the cloaking assembly **10** and an automobile 'A' located behind the column C on the object-side **102** of the cloaking assembly **10** in the +Y direction. The column C has a height dimension in the Z direction (increasing height in the −Z direction) greater than the height h of the cloaking device. FIG. **4** is a side view from the +Y direction of the cloaking assembly **10** shown in FIG. **3** and shows the portion of the column C that is within the CR **200** is not visible and the automobile A located behind the column C in the +Y direction is visible to an observer viewing the cloaking assembly **10** in the +Y direction. Accordingly, the column C positioned within the CR **200** is not visible to an observer viewing the image-side **104** of the cloaking assembly **10** and an image of the entire automobile A (both the obscured portion and the visible portions) is visible to the observer viewing the image-side **104**. Although column C in FIGS. **3**-**4** is separate from the CR boundary planes **118**, **128**, **138**, **148**, i.e., column C is a separate object from the cloaking device **10**, it should be appreciated that column C may be structurally part of the cloaking device **10** and have an outer surface that provides or is equivalent to the CR boundary planes **118**, **128**, **138**, **148** with outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, respectively.

Referring now to FIGS. **1**-**5**, FIG. **5** shows embodiments of a cloaking assembly **12** with an enlarged CR **200**. Particularly, the cloaking assembly components **110**, **120**, **130**, **140** are arranged such that the cloaking assembly components **110**, **130** are spaced apart in the Y direction from the cloaking assembly components **120**, **140**, and a distance 'd' is between the inward facing surfaces **114**, **124**, and between the inward facing surfaces **134**, **144**. The area of the CR **200** in the X-Y plane is increased by the width 'w' times the distance d (w×d). The volume of the CR **200** is increased by the width w times the distance d times the height h (FIG. **4**) of the CR **200** (w×d×h). While FIG. **5** illustrates four cloaking assembly components **110**, **120**, **130**, **140**, it should be appreciated that the four CR boundary planes **118**, **128**, **138**, **148**, and the four half mirrors **115**, **125**, **135**, **145** can be contained within any number of cloaking assembly components. For example, in embodiments, the cloaking assembly components **110** and **130** may be a single cloaking assembly component and the two cloaking assembly components **120** and **140** can be a single cloaking assembly component.

As shown in the FIG. **5**, light lo is reflected from the target object O, travels in the −Y direction and is incident on and transmitted through the outward facing surfaces **112**, **132**. Light lo reflected from the obscured portions of the object located directly behind the CR in the +Y direction is reflected by the outward facing mirror surfaces **118***a*, **138***a* in the +X and −X direction, respectively. The reflected light lo in the +X and −X directions is incident on the half mirrors **115**, **135** respectively. The half mirrors **115**, **135** are p-polarization half mirrors and reflect the s-mode is of the light lo and transmit the p-mode lp of the light lo. The s-polarized light ls reflected by the half mirrors **115**, **135** in the −Y direction is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** are also p-polarization mirrors that reflect the s-polarized light ls traveling in the −Y direction into the −X and +X directions, respectively. The s-polarized light ls traveling in the −X and +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively, and the outward facing mirror surfaces **128***a*, **148***a* reflect the incident s-polarized light ls in the −Y direction. The s-polarized light reflected in the −Y direction by the outward facing mirror surfaces **128***a*, **148***a*, forms an image of the obscured portion of the object located behind the CR **200** in the +Y direction that is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. Light lo reflected from the visible portions of the target object O not located behind the CR **200** in the +Y direction is incident on and transmitted through the outward facing surfaces **112**, **132**. The transmitted light lo is incident on the p-polarization half mirrors **115**, **135**, and the half mirrors **115**, **135** reflect the s-mode is of the incident light lo in the +X and −X directions, respectively, and transmit the p-mode lp of the incident light lo in the −Y direction. The p-polarized light lp transmitted through the half mirrors **115**, **135** in the −Y direction is incident on and transmitted through the p-polarization half mirrors **125**, **145**, respectively, in the −Y direction. The p-polarized light lp transmitted in the −Y direction through the half mirrors **125**, **145**, forms an image of the visible portions of the target object O not located behind the CR **200** in the +Y direction that is visible to an observer viewing the image side **104** of the cloaking assembly **12**. Accordingly, an image I of the entire target object O (both the obscured portion and the visible portions) is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. It should be appreciated that half mirrors **115**, **125**, **135**, **145**, can be s-polarization half mirrors and the reflected and transmitted portions of the reflected light lo discussed above will be reversed. Also, it should be appreciated that the one or more of optical filters **125***a*, **125***b*, **145***a*, **145***b* may be included. However, the human eye cannot distinguish between s-polarized light, p-polarized light or circularly polarized light and the image I of the entire object O will be visible to an observer viewing the image-side **104** of the cloaking assembly **12**.

Referring now to FIGS. **1**-**7**, a top perspective view and a side view of a cloaking device according to embodiments (as discussed with respect to FIG. **5**) are shown in FIGS. **6**-**7**, respectively. Specifically, FIG. **6** is a top perspective view of a first article in the form of a column 'C1' and a second article in the form of a column 'C2' within the CR **200** of the cloaking assembly **12** and the automobile 'A' located behind the columns C1, C2 on the object-side **102** of the cloaking assembly **12** in the +Y direction. The column C1 has a first height dimension in the Z direction and the column C2 has a second height dimension that is greater (in the −Z direction) than the first height dimension of column C**1**. The first height dimension of column C**1** and the second height dimension of column C**2** are both greater than the height h of the cloaking assembly **12**. FIG. **7** is a side view from the +Y direction of the cloaking assembly **12** shown in FIG. **6** and shows the image-side **104**. Portions of column C1 and column C2 within the CR **200** are not visible and automobile A located behind column C1 and column C2 in the +Y direction is visible to an observer viewing the image-side **104** of the cloaking assembly **12**. Although columns C1, C2 in FIGS. **6**-**7** are separate from the CR boundary planes **118**, **128**, **138**, **148**, i.e., columns C1, C2 are separate objects from the cloaking device **12**, it should be appreciated that columns C**1**, C**2** may be structurally part of the cloaking device **12** and have an outer surface that provides or is equivalent to the CR boundary planes **118**, **128**, **138**, **148** with outward facing mirror surfaces **118***a*, **128***a*, **138***a*, **148***a*, respectively.

Referring to FIG. **8**, embodiments of a cloaking device that can display additional images in conjunction with the images depicted in FIGS. **1**, **4**, **5** and **7** are shown. Particularly, FIG. **8** shows an item in the form of the number '1' (item 1) and an item in the form of the number '2' (item 2) located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo reflected from item 1 and item 2 is incident on and transmitted through the outer end surfaces **126**, **146** in the −X, +X directions, respectively. The light lo transmitted through the outer end surfaces **126**, **146** is incident on the half mirrors **125**, **145**, respectively. The half mirrors **125**, **145** (p-polarization half mirrors) transmit the p-mode lp of the light lo in the −X, +X directions, respectively, and reflect the s-mode is of the light lo into the −Y direction. The transmitted p-polarized light lp in the −X, +X directions is incident on the outward facing mirror surfaces **128***a*, **148***a*, respectively. The outward facing mirror surfaces **128***a*, **148***a*, reflect the incident p-polarized light lp into the −Y direction. The s-polarized light ls reflected by the half mirror **125** in the −Y direction forms a reversed '1' image on the right hand side of the outward facing surface **122** and the s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed '2' image on the left hand side of the outer facing surface **142**. The p-polarized light lp reflected by the outward facing mirror surface **128***a* into the −Y direction forms a reversed '1' image on the left hand side of the outward facing surface **122** and the p-polarized light lp reflected by the outward facing mirror surface **148***a* into the −Y direction forms a reversed '2' image on the right hand side of the outer facing surface **142**. It should be appreciated that the display of additional images as depicted in FIG. **8** in conjunction with images as depicted in FIGS. **1**, **4**, **5** and **7** can be used as part of a heads-up display, a warning system (signal) that an object is located on the object side of the cloaking device, etc.

Referring to FIGS. **1**-**10**, embodiments of a cloaking device with a cloaking assembly **14** having items in the form of '1', '2', '3', '4' adjacent to the outer end surfaces **126**, **146**, **116**, **136**, respectively are shown in FIG. **9**. FIG. **10** is a side view of the cloaking assembly **14** illustrated in FIG. **9** with reversed images of item 1 and item 2, in conjunction with the image of the automobile A, visible on the image-side **104** of the cloaking assembly **14**. It should be appreciated that items 1, 2, 3, 4 depicted in FIGS. **9**-**10** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **9** could be oriented in the Y-Z plane in order to provide reversed images of items 1, 2 on the image side **104** (X-Z plane) in FIG. **10**. It should also be appreciated that reversed images of item 3 and item 4 can be formed or provided on the object-side **102** of the cloaking assembly **14** in a similar manner as the reversed images of item 1 and item 2 are formed on the image-side **104**.

Referring to FIGS. **1**-**8** and **11**, embodiments of a cloaking device that can selectively display images in conjunction with the images depicted in FIGS. **1**, **4**, **5** and **7** are shown. Particularly, FIG. **11** shows an item in the form of the number '1' and an item in the form of the number '2' located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo from item 1 is incident on an s-polarizer **150**. The s-polarizer **150** allows the s-mode is of the incident light lo to pass through in the −X direction. The s-polarized light ls is incident on and reflected by the p-polarization half mirror **125** into the Y direction and no light is transmitted through or beyond the p-polarization half mirror **125** in the −X direction. Accordingly, a reversed image of item 1 is formed only on the right hand side of the outward facing surface **122**. The light lo from item 2 is transmitted through the outer end surface **146** in the +X direction and is incident on the p-polarization half mirror **145**. The p-polarization half mirror **145** transmits the p-mode lp of the incident light lo in the +X direction and reflects the s-mode is of the incident light lo in the −Y direction. The p-polarized light lp in the +X direction is incident on the outward facing mirror surface **148***a*. The outer facing mirror surface **148***a* reflects the incident p-polarized light lp in the −Y direction. The s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed item 2 image on the left hand side of the outer facing surface **142**. The p-polarized light lp reflected by the outer facing mirror surface **148***a* into the −Y direction provides a reversed item 2 image on the right hand side of the outer facing surface **142**.

Referring to FIGS. **1**-**8** and **11**-**13**, embodiments of a cloaking device with a cloaking assembly **16** having items in the form of '1' and '2' adjacent to the outer end surfaces **126**, **146**, respectively, and the s-polarizer **150** adjacent the outer end surface **126**, are shown in FIG. **12**. FIG. **13** is a side view of the cloaking assembly **16** illustrated in FIG. **12** with the reversed image of item 1 visible on the right hand side of the outer facing surface **122** of the cloaking assembly component **120** and the reversed image of item 2 visible on the left hand side and right hand side of the outward facing surface **142** of the cloaking assembly components **140** shown in conjunction with the image of the automobile A. It should be appreciated that items 1, 2 depicted in FIG. **12** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **12** could be oriented in the Y-Z plane in order to provide the reversed images of items 1, 2 on the image-side (**104**) (X-Z plane) shown in FIG. **13**.

Referring to FIGS. **1**-**8** and **14**, another embodiment of a cloaking device that can selectively display additional images in conjunction with the images depicted in FIGS. **1**,

4, **5** and **7** is shown. Particularly, FIG. **14** shows an item in the form of the number '1' and an item in the form of the number '2' located adjacent to the outer end surfaces **126**, **146**, respectively, in the +X, −X directions, respectively. Light lo reflected from the item 1 is incident on a p-polarizer **152** which allows p-polarized light lp to pass through in the −X direction. The p-polarized light lp is incident on the p-polarization half mirror **125**. The incident p-polarized light lp in the −X direction is transmitted through the p-polarization half mirror **125** in the −X direction and there is no s-polarized light is to be reflected by the p-polarization half mirror **125** in the −Y direction. The p-polarized light lp transmitted through the p-polarization half mirror **125** is incident on the outward facing mirror surface **128***a* and the outward facing mirror **128***a* reflects the p-polarized light lp into the −Y direction. Accordingly, a reversed image of item 1 is formed only on the left hand side of the outward facing surface **122**. The light lo reflected from item 2 is transmitted through the outer end surface **146** in the +X direction and is incident on the p-polarization half mirror **145**. The p-polarization half mirror **145** transmits the p-mode lp of the incident light lo in the +X directions and reflects the s-mode ls of the incident light lo into the −Y direction. The p-polarized light lp in the +X is incident on the outer facing mirror surface **148***a*. The outer facing mirror surface **148***a* reflects the incident p-polarized light lp into the −Y direction. The s-polarized light ls reflected by the half mirror **145** in the −Y direction forms a reversed 2 on the left hand side of the outer facing surface **142** and the p-polarized light lp reflected by the outer facing mirror surface **148***a* in the −Y direction forms a reversed 2 image on the right hand side of the outer facing surface **142**.

Referring to FIGS. **1**-**8** and **14**-**16**, embodiments of a cloaking device with a cloaking assembly **18** having items 1 and items 2 adjacent to the outer end surfaces **126**, **146**, respectively, and the p-polarizer **152** adjacent to the outer end surface **126**, are shown in FIG. **15**. FIG. **16** is a side view of the cloaking assembly **18** illustrated in FIG. **15** with the single reversed image of item 1 visible on the left hand side of the outer facing surface **122** of the cloaking assembly component **120** and the reversed image of item 2 visible on the left hand side and right hand side of the outward facing surface **142** of the cloaking assembly components **140** in conjunction with the image of the automobile A. It should be appreciated that items 1, 2 depicted in FIG. **15** are shown for illustrative purposes only, i.e. the items 1, 2 in FIG. **15** could be oriented in the Y-Z plane in order to provide the reverse images of items 1, 2 on the image-side **104** (X-Z plane) shown in FIG. **16**.

Referring to FIGS. **1**, **2**, **5**, **8**-**17**, embodiments of an A-pillar of a vehicle being cloaked by a cloaking device are shown. Particularly, FIG. **17** shows a cloaking device **19** cloaking a portion of an A-pillar P of a vehicle V. A portion of the A-pillar P is positioned within a CR **200** (not shown) of the cloaking device **19** and a portion of the A-pillar P extends beyond the cloaking device and is covered with trim T. Illustrated outside of the vehicle V is a target object O in the form of pedestrian. A portion of the pedestrian O is visible through a side window of the vehicle V and a portion of the pedestrian is visible "through" the A-pillar P cloaked by the cloaking device **19**. The cloaking device **19** redirects light reflected from the pedestrian O around the A-pillar P positioned within the CR **200** of the cloaking device **19** and forms an image I of the pedestrian O on an image-side **104** of the cloaking device **19** that is visible to an occupant of the vehicle V looking towards the pedestrian O. Accordingly, light from the pedestrian O appears to pass through the A-pillar P and a blind spot typically created by the A-pillar P is not present. In embodiments, the A-pillar P itself serves as the CR **200**, i.e. the A-pillar P has an outer surface with one or more outer facing mirror surfaces that assist in redirecting light from the pedestrian) around the A-pillar P. It should be appreciated that cloaking of the A-pillar P with the cloaking device **19** and removing the blind spot produced by the A-pillar P is performed without the use of metamaterials, video images, cameras, sophisticated electronics, etc.

Referring to FIGS. **18**-**19**, alternative embodiments of cloaking devices are shown. Specifically, FIG. **18** shows a cloaking device **20** with a circular CR **202** having an outer mirror surface **204** with half mirrors **206**, **208** around the outer mirror surface **204** having a circular shape. In embodiments, the CR **202** is provided by an object to be cloaked itself, e.g., an A-pillar, that has an outer mirror surface **204**. The cloaking device shown in FIG. **18** can increase the field of view for an observer viewing the cloaking device **20** in the +Y direction. FIG. **19** shows a cloaking device **30** with a circular CR **302** having an outer mirror surface **304** with half mirrors **306**, **308** and optical components **310**, **312** such as lenses. In embodiments, the CR **302** is provided by an object to be cloaked itself, e.g., an A-pillar, that has an outer mirror surface **304**. The cloaking device shown in FIG. **19** allows for an external view from an object located behind the CR **302** (+Y direction) to be manipulated to increase a field of view or to normalize a distorted image.

The cloaking devices described herein may be used to cloak vehicle articles such as a vehicle A-pillar, and remove a "blind spot" caused by the vehicle article. It will be understood that the term "blind spot" as used herein refers to an area around the vehicle that cannot be directly observed by a driver while operating the vehicle. The terms "object," "article," and "item" may interchangeably refer to a visual object or image (2D or 3D) that reflects light or transmits light and the team "light from" may refer to "light reflected from" or "light transmitted from." The terms "generally," "approximately," and "about" may be utilized herein to represent the inherent degree of uncertainty that may be attributed to any quantitative comparison, value, measurement, or other representation. These terms are also utilized herein to represent the degree by which a quantitative representation may vary from a stated reference without resulting in a change in the basic function of the subject matter at issue.

While particular embodiments have been illustrated and described herein, it should be understood that various other changes and modifications may be made without departing from the spirit and scope of the claimed subject matter. Moreover, although various aspects of the claimed subject matter have been described herein, such aspects need not be utilized in combination. It is therefore intended that the appended claims cover all such changes and modifications that are within the scope of the claimed subject matter.

What is claimed is:

1. A cloaking device comprising:

an object-side and an image-side;

a cloaking region (CR) boundary plane having an outward facing mirror surface and an inward facing opaque surface;

a CR at least partially bounded by the inward facing opaque surface of the CR boundary plane;

a half mirror spaced apart from and generally parallel to the outward facing mirror surface;

wherein light from an object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR to form an image of the object on the image-side of the cloaking device such that the light from the object appears to pass through the CR.

2. The cloaking device of claim **1**, wherein the half mirror is selected from a p-polarization half mirror and an s-polarization half mirror.

3. The cloaking device of claim **1**, further comprising an article positioned within the CR, wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the article to form the image of the object on the image-side of the cloaking device such that the article appears transparent.

4. The cloaking device of claim **3**, wherein the article is a vehicle A-pillar.

5. The cloaking device of claim **1**, further comprising:

at least two CR boundary planes positioned non-planar to each other, each of the at least two CR boundary planes having an outward facing mirror surface and an inward facing opaque surface, the CR at least partially bounded by the inward facing opaque surfaces of the at least two CR boundary planes;

at least one quarter-wave plate positioned on or adjacent to the image side; and

at least two half mirrors spaced apart from and generally parallel to the outward facing mirror surfaces, respectively; such that a half mirror of the at least two half mirrors is spaced apart from and generally parallel to each of the outward facing mirror surfaces;

wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR by the at least two outward facing mirror surfaces and the at least two half mirrors, and the image of the object is formed on the image-side of the cloaking device such that the light from the object located on the object-side of the cloaking device appears to pass through the CR.

6. The cloaking device of claim **5**, wherein the at least two CR boundary planes are positioned orthogonal to each other.

7. The cloaking device of claim **6**, wherein the light from the object on the object-side of the cloaking device is reflected by a first outward facing mirror surface, a first half mirror positioned parallel to the first outward facing mirror surface, a second half mirror positioned orthogonal to the first half mirror, a second outward facing mirror surface positioned parallel to the second half mirror, and transmitted through the at least one quarter-wave plate before forming the image of the object on the image-side of the cloaking device.

8. The cloaking device of claim **7**, further comprising a vehicle article positioned within the CR, wherein the light from the object located on the object-side of the cloaking device and obscured by the CR is redirected around the CR and the vehicle article to form the image of the object on the image-side of the cloaking device and the vehicle article appears transparent.

9. The cloaking device of claim **5**, further comprising an end side, wherein light from an item positioned adjacent to the end side forms an image of the item on the image-side of the cloaking device.

10. A cloaking device for cloaking an article of a vehicle comprising:

a cloaking assembly comprising:

an object-side and an image-side;

at least two cloaking region (CR) boundary planes located at least partially between the object-side and the image-side, the at least two CR boundary planes positioned non-planar to each other and each of the at least two CR boundary planes having an outward facing mirror surface and an inward facing opaque surface;

a CR bounded by the inward facing opaque surfaces of the at least two CR boundary planes;

at least two half mirrors located at least partially between the object-side and the image-side, each of the at least two half mirrors spaced apart from and generally parallel to one of the outward facing mirror surfaces;

at least one quarter-wave plate positioned on or adjacent to the image side;

and

a vehicle article positioned within the CR;

wherein light from an object located on the object-side of the cloaking assembly and obscured by the CR is redirected around the CR and forms an image of the object on the image-side of the cloaking assembly such that the vehicle article appears to be transparent.

11. The cloaking device of claim **10**, wherein the vehicle article is a vehicle A-pillar.

12. The cloaking device of claim **10**, wherein the light from the object is reflected by a first outward facing mirror surface, a first half mirror oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror and transmitted through the at least one quarter-wave plate before forming the image on the image-side of the cloaking assembly.

13. The cloaking device of claim **12**, further comprising an end surface, wherein light from an item located adjacent to the end surface passes through the cloaking assembly and forms an image of the item on the image-side of the cloaking assembly.

14. The cloaking device of claim **13**, wherein a p-mode or an s-mode of the light from the item is reflected from the second half mirror before forming the image of the item on the image-side of the cloaking assembly.

15. The cloaking device of claim **13**, wherein a p-mode or an s-mode of the light from the item is transmitted through the second half mirror and reflected by the second outward facing mirror surface before forming the image of the item on the image-side of the cloaking assembly.

16. A cloaking device comprising:

four cloaking region (CR) boundary planes positioned non-planar to each other, each of the four CR boundary planes having an outward facing mirror surface and an inward facing opaque surface;

a CR bounded by the inward facing opaque surfaces of the four CR boundary planes;

an article located at least partially within the CR;

four half mirrors spaced apart from and generally parallel to the outward facing mirror surfaces, respectively, such that a half mirror of the four half mirrors is spaced apart from and generally parallel to each of the outward facing mirror surfaces;

wherein light from an object on an object-side of the cloaking device is redirected around the CR and appears as an image on an image-side of the cloaking device and is visible to an observer viewing the image-side of the cloaking device, and wherein the article within the CR is not visible to the observer viewing the image-side of the cloaking device such that the article within the CR appears transparent to the observer viewing the image-side of the cloaking device.

17. The cloaking device of claim **16**, wherein the light from the object is reflected by a first of the outward facing mirror surfaces, a first of the outward facing mirror surfaces, a first of the four half mirrors oriented generally parallel to the first outward facing mirror surface, a second half mirror oriented generally orthogonal to the first half mirror and a second outward facing mirror surface oriented generally parallel to the second half mirror before forming the image on the image-side of the cloaking device.

18. The cloaking device of claim **17**, wherein the article is a vehicle A-pillar.

19. The cloaking device of claim **18**, further comprising an end side, wherein light from an item located adjacent to the end side is reflected by at least one of the second half mirror and the second outward facing mirror surface and forms an image of the item on the image-side of the cloaking device.

20. The cloaking device of claim **19**, wherein the image of the item is selectively formed on the image-side of the cloaking device.

(57) **ABSTRACT**

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

This application is a continuation-in-part of prior U.S. application Ser. No. 14/509772 filed 8 Oct. 2014 which claims the benefit of U.S. Provisional Application No. 61/889,894 filed 11 Oct. 2013, the disclosures of all of which are incorporated by reference herein in their entirety.

TECHNICAL FIELD

The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

In some embodiments, the power receiver further comprises an elevated terminal.

In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** illustrates a first exemplary embodiment of a power receiver.

FIG. **2** illustrates a second exemplary embodiment of a power receiver.

FIG. **3** illustrates a third exemplary embodiment of a power receiver.

FIG. **4** illustrates a fourth exemplary embodiment of a power receiver.

FIG. **5** illustrates a fifth exemplary embodiment of a power receiver.

FIG. **6**A is an exploded perspective view of an exemplary ground antenna array for the power receiver.

FIG. **6**B is a perspective view of an assembled ground antenna array before being deployed.

FIG. **6**C is a perspective view of an assembled ground antenna array after being deployed.

FIG. **7**A is a side view of an insertion tool for installing the ground antenna array.

FIG. **7**B is a top view of the insertion tool for installing the ground antenna array.

FIG. **7**C is a bottom view of the insertion tool for installing the ground antenna array.

DETAILED DESCRIPTION

Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral **10**. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1-200 Hertz. For example, the resonant transformer **30** may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**, **100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the

power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **85**. It should be appreciated that the electrical ground **85** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The ground terminal **25** may comprise a ⅝-inch×8-foot copper ground rod, such as the ERICO 615880UPC. The elevated terminal **15** may comprise a 90% copper mesh formed into a hemisphere with a radius of about 9 inches. The elevated terminal **15** may be elevated at a height of approximately 6 feet above the ground.

The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about 10 and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allanson transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part #TC 103-17-125). The resonant transformer **30** is used in a step-down configuration. The center tap of the resonant transformer **30** may optionally be connected to a ground.

An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40** of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

The pulse generator **65** comprises a square wave generator **70**, such as a Sinometer VC2002 function signal generator, and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required.

The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The battery may comprise a 12 V, 7.0 A/H sealed lead acid battery, such as the ELB 1270A by Lithonia Lighting. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

The step-up transformer **80** may comprise a Transco 15 kV, 30 mA neon sign transformer (part #S15612). The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. A suitable spark gap electrode pair is the Information Unlimited SPARK05 ¼-inch×1-inch tungsten electrodes. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. A suitable rectifier is the Micro Commercial Components 10 amp, 1000 volt bridge rectifier (Part #GBJL 1010). The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. A filter capacitor **120** removes unwanted frequencies from the DC current. A suitable capacitor **120** is Cornell Dubilier 1000uF 450VDC capacitor (part #383LX102M450N082). The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, such as a Tracer 4215 BN MPPT Solar Charge Controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. A suitable inverter **135** is the 1500 W Pure Sine power inverter (AIMS) (part #PWRI1500125).The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

FIG. **5** illustrates a power receiver **10** according to another embodiment. The power receiver **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

FIGS. **6A-6C** illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6B**. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270** extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6B** illustrates the ground antenna array **200** before deployment. FIG. **6C** illustrates the ground antenna array in a deployed configuration.

Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

What is claimed is:

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant transformer connected to a ground terminal disposed below the surface of the earth;

an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce current flow from the ground terminal through the primary winding of the transformer; and

a power conversion circuit connected to a secondary winding of the resonant transformer to convert electrical current flowing through the secondary winding to a desired form.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformer is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro-resonant transformer.

4. The power receiver of claim **1** further comprising an elevated terminal, and wherein the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

5. The power receiver of claim **4** wherein said resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

6. The power receiver of claim **4** comprising multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

7. The power receiver of claim **6** wherein the resonant transformers have different resonant frequencies.

8. The power receiver of claim **7** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

9. The power receiver of claim **1** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

10. The power receiver of claim **1** wherein the impulse generator comprises a solid state spark generator.

11. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

12. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:

a resonant circuit connected to a ground terminal disposed below the surface of the earth, said resonant circuit having a resonant frequency below 200 Hertz

an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit; and

a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form.

13. The power receiver of claim **12** wherein the impulse generator comprises:

a pulse generator for generating low voltage pulses;

a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;

a spark gap connected between the step-up transformer and resonant circuit to generate a spark responsive to the high voltage impulses from the step-up transformer.

14. The power receiver of claim **12** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in parallel with the primary winding.

15. The power receiver of claim **12** wherein the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

16. The power receiver of claim **12** wherein the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel.

17. The power receiver of claim **16** wherein the resonant transformers have different resonant frequencies.

18. The power receiver of claim **17** wherein the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

An apparatus and method for powering a platform from an ambient electrostatic gradient are disclosed. The apparatus includes an ion powered platform comprises a platform body, an electrical load carried by the platform body; and an electrically conductive probe. The electrically conductive probe is electrically connected to the electrical load at a first point thereon and adapted to generate electrical energy from an ambient electrostatic field gradient. The electrically conductive probe extends from the electrical load such that a second point thereon is vertically displaced from the first point and on the opposite connection of the load. The method includes comprises positioning a first point on an electrically conductive probe at least a predetermined vertical distance from a second point on the electrically conductive probe at which the electrically conductive probe is electrically connected to the electrical load; initiating relative movement between an ambient atmosphere and the electrically conductive probe; and supplying energy generated by an electrical potential created by initiating the relative movement to the electrical load.

ION POWERED PLATFORM

BACKGROUND OF THE INVENTION

[0001] 1. Field of the Invention

[0002] The present invention pertains to an electronic power supply, and, more particularly, to a method and apparatus for powering an electronic device from an ambient (i.e., naturally occurring, as opposed to man-made) electrostatic field gradient.

[0003] 2. Description of the Related Art

[0004] Technological advances enable ever smaller, more capable tools and devices. Electronic components continue to shrink in size while increasing the power of their applications. One example of this phenomenon is the ubiquitous microprocessor that forms the heart of the personal computer. However, the fabrication and design techniques underpinning this phenomenon are applicable to other active and passive electronic components. At the same time, electronic components are finding their way into a broader range of applications. These factors contribute to a discernible trend toward smaller, more capable, and more powerful tools and devices in many areas.

[0005] One factor nevertheless continues to retard this trend—power. All these electronic components require electrical power. Furthermore, their power consumption typically rises as the size decreases and the capability increases. Power is typically supplied either by a battery or through an electrical cord connected to a powered electrical grid or a generator. Batteries continue to be relatively large and heavy despite recent, significant advances in battery technology. Connection to a power grid and/or generator brings numerous limitations regarding portability and convenience arising from the umbilical/electrical cord.

[0006] The present invention is directed to resolving, or at least reducing, one or all of the problems mentioned above.

SUMMARY OF THE INVENTION

[0007] The invention includes an apparatus and method for powering a platform from an ambient electrostatic gradient.

[0008] Thus, in a first aspect of the invention, an ion powered platform comprises a platform body, an electrical load carried by the platform body; and an electrically conductive probe. The electrically conductive probe is electrically connected to the electrical load at a first point thereon and adapted to generate electrical energy from an ambient electrostatic field gradient. The electrically conductive probe extends from the electrical load such that a second point thereon is vertically displaced from the first point and on the opposite connection of the load.

[0009] In a second aspect, the invention includes a method for powering an electrical load on an ion powered platform with ions. The method comprises positioning a first point on an electrically conductive probe at least a predetermined vertical distance from a second point on the electrically conductive probe at which the electrically conductive probe is electrically connected to the electrical load; initiating relative movement between an ambient atmosphere and the electrically conductive probe; and supplying energy generated by an electrical potential created by initiating the relative movement to the electrical load.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] The invention may be understood by reference to the following description taken in conjunction with the accompanying drawings, in which like reference numerals identify like elements, and in which:

[0011] **FIG. 1** conceptually depicts, in a partially sectioned perspective view, one particular embodiment of an ion powered platform constructed in accordance with the present invention;

[0012] **FIG. 2A** to **FIG. 2F** depicts alternative embodiments of the electrically conductive probe of the ion powered platform of **FIG. 1** implemented in electrically conductive solids;

[0013] **FIG. 3** conceptually depicts an alternative embodiment in which an ionization source is located at the distal end of an electrically conductive probe;

[0014] **FIG. 4** conceptually depicts another alternative embodiment employing a secondary ionization source to enhance ionization efficiency;

[0015] **FIG. 5**A and **FIG. 5B** illustrate the operation of embodiments employing a primary ionization source and a primary and a secondary ionization source, respectively;

[0016] **FIG. 6A** and **FIG. 6B** conceptually depict yet another alternative embodiment in which the ion powered platform is stationary;

[0017] **FIG. 7**A and **FIG. 7B** conceptually depict yet another alternative embodiment in which the electrically conductive probe is implemented in an ionized fluid medium; and

[0018] **FIG. 8** illustrates a method practiced in accordance with one aspect of the present invention.

[0019] While the invention is susceptible to various modifications and alternative forms, the drawings illustrate specific embodiments herein described in detail by way of example. It should be understood, however, that the description herein of specific embodiments is not intended to limit the invention to the particular forms disclosed, but on the contrary, the intention is to cover all modifications, equivalents, and alternatives falling within the spirit and scope of the invention as defined by the appended claims.

DETAILED DESCRIPTION OF THE INVENTION

[0020] Illustrative embodiments of the invention are described below. In the interest of clarity, not all features of an actual implementation are described in this specification. It will of course be appreciated that in the development of any such actual embodiment, numerous implementation-specific decisions must be made to achieve the developers' specific goals, such as compliance with system-related and business-related constraints, which will vary from one implementation to another. Moreover, it will be appreciated that such a development effort, even if complex and time-consuming, would be a routine undertaking for those of ordinary skill in the art having the benefit of this disclosure.

[0021] **FIG. 1** conceptually illustrates, in a partially sectioned perspective view, one particular embodiment of an ion powered platform **100** constructed in accordance with the present invention. For instance, Earth's atmosphere includes an ambient electrostatic field gradient of approximately 100 to 300 volts per meter over most of Earth's surface, although this varies with, for instance, altitude and weather conditions. The ion powered platform **100** extends an electrically conductive probe **105** at least a predetermined vertical distance to utilize this electrostatic field gradient to power an electrical load **110**. The movement of the electrically conductive probe **105** through the electrostatic field gradient causes individual molecules in the atmosphere to ionize, thereby generating an electrical potential across the electrically conductive probe **105**. This electrical potential is then harnessed to power the electrical load **110**. Note that the movement of the electrically conductive probe **105** through the electrostatic field gradient is a relative movement. In other words, the atmosphere streams past the conductive probe **105**. This can result from a motive force imparted to or by the ion powered platform **100** causing it to move. Alternatively, this can result from a wind blowing across a stationary, or slow moving, electrically conductive probe **105**.

[0022] More particularly, the ion powered platform **100** comprises a platform body **115**, the electrical load **110** carried by the platform body **115**, and the electrically conductive probe **105**. The electrically conductive probe **105** is electrically connected to the electrical load **110** and is electrically grounded at a first point **140**. In the illustrated embodiment, the first point **140** is grounded by electrically connecting it to an electrically conductive patch **145** on the fuselage **170** of the airframe **160**. Note that, if the fuselage **170** is fabricated from an electrically conductive material, the first point **140** can be grounded at any point thereon. The electrically conductive probe **105** extends from the electrical load **110** such that a second point **150** thereon is vertically displaced from the first point **140**. The electrically conductive probe **105** is adapted to generate electrical energy from an ambient electrostatic field gradient, as is discussed further below

[0023] The invention admits wide variation in the implementation of the platform body **115**. In the illustrated embodiment, the platform **100** is a flying vehicle, and so the platform body **115** includes an airframe **160** to which the electrical load **110** is mounted and a fuselage **170**. Thus, the platform body **115** of the illustrated embodiment houses the electrical load **110**, but this is not necessary to the practice of the invention. The electrical load **110** may be left exposed to the ambient environment in some alternative embodiments. Indeed, the ion powered platform **100** may be implemented in alternative embodiments as, for example, a reconnaissance drone or a ground-based robotic vehicle. The ion powered platform **100** need not even be a vehicle, but might alternatively be, e.g., a container made of wood, metal, plastic, or some other material.

[0024] The identity of the electrical load **110** will be implementation specific. In the illustrated embodiment, the electrical load **110** is a fuse capacitor. The fuse capacitor charges with electrical energy received from the electrically conductive probe **105** at the first point **140**. When the fuse capacitor charges sufficiently, the flying submunition is armed and ready to detonate. However, the invention admits variation in the implementation of the electrical load **110** as wide as that for the ion powered platform body **115**. The electrical load **110** may be, for example, in alternative embodiments, a motor, or some high-power, short-burst communications circuitry. The motor may also be a high voltage or a low voltage motor, depending on the implementation.

[0025] The invention also permits wide variation in implementing the electrically conductive probe **105**. The shape and/or geometry of the electrically conductive probe **105** is not material to the practice of the invention. Alternative embodiments are illustrated in **FIG. 2A** to **FIG. 2E**. The electrically conductive probe **105** of **FIG. 1** may be, for instance:

[0026] an electrically conductive fiber **105***a*, as shown in **FIG. 2A**;

[0027] an electrically conductive ribbon **105***b*, as shown in **FIG.** 2B, for instance, woven or otherwise fabricated from electrically conductive fibers (e.g., the electrically conductive fiber **105***a*) or a flexible material coated by metal or a metallized polymer;

[0028] an electrically conductive rod **105***c*, as shown in **FIG.** 2C, such as a metallized glass rod;

[0029] an array **105***d* of electrically conductive rods (e.g., the electrically conductive rod **105***c*) ribbons (e.g., the electrically conductive ribbon **105***b*), or electrically conductive fibers (e.g, the electrically conductive fiber **105***a*) as shown in **FIG. 2D**;

[0030] an electrically conductive sheet **105***e*, as shown in **FIG.** 2E, fabricated from, e.g., a metal or electrically conductive composite material; or

[0031] an electrically conductive ring **105***f*, as shown in **FIG.** 2F, fabricated from, e.g., a metal or an electrically conductive composite material.

[0032] Thus, the electrically conductive probe **105** may by flexible (e.g., as are the electrically conductive fiber **105***a* and electrically conductive ribbon **105***b*) or rigid (e.g., like the electrically conductive rod **105***c* and electrically conductive sheet **105***e*). Note also that the vertical displacement between the two most vertically distant points on the electrically conductive probe **105** contributes more significantly to its operation than its actual shape and/or geometry.

[0033] The vertical displacement between the two most vertically distant points on the electrically conductive probe **105** will be implementation specific. The vertical displacement will primarily be a factor of the power requirements of the electrical load and the electrostatic field gradient, applied in light of commonly accepted engineering principles. For instance, as was previously mentioned, Earth's electrostatic field gradient varies from approximately 100 to approximately 300 volts per meter in fair weather and at sea level. However, these values will vary with altitude and weather—

bad weather, for example, can greatly increase the magnitude. Note that the invention may find extraterritorial application, e.g., on Venus, Mars, or Europa, whose ambient electrostatic field gradients may vary from that of Earth's. Similarly, the power requirements of the electrical load **110** may vary over time as the ion powered platform **100** enters differing operational modes. Similarly, some applications might be more tolerant of power supply faults than are other, thereby providing greater latitude in design.

[**0034**] Another important factor is the volume of ionized air. Greater volumes tend to produce a greater electrical potential. For this reason, implementations of the electrically conductive probe **105** that maximize this volume of ionized air may be generally preferred for most embodiments. The array **105***d* in **FIG. 2D** might therefore be preferred over the electrically conductive rod **105***c* in **FIG. 2C**. The electrically conductive ribbon **105***b* in **FIG. 2B** might also generally be preferred over the electrically conductive fiber **105***a* in **FIG. 2A**. However, each implementation may be different, and this principle is not universally applicable to all embodiments.

[**0035**] Still referring to **FIG. 1**, in one particular implementation, the electrically conductive element **105** is an electrically conductive fiber, or "streamer," extending from the ion powered platform **100**. The first and second points **140**, **150** are separated by 100 meters and generate a potential difference of 10,000 volts. In the illustrated embodiment, as was mentioned, this potential is used to charge a fuse capacitor in a flying submunition. However, in alternative embodiments, a high voltage capacitor could be used to, for instance, provide current to a switching circuit to create lower voltage higher current pulses adequate to run a small motor. By utilizing this larger current capability, the ability to deliver energy for useful work is made possible.

[**0036**] Design constraints may make it difficult or impractical to provide the requisite vertical displacement in some implementations. One such embodiment **300** is shown in **FIG. 3**. In these embodiments, the ionizing effect of the electrically conductive probe **105**, shown in **FIG. 1**, can be enhanced by including an ionization source **305** at the point **150** of the electrically conductive probe **105** most distal from the electrical load **110**. For embodiments where the point **140** does not contact the electrical ground **145**, the ionization source **305** may be located anywhere on the electrically conductive probe **105**, but the point **150** most distal the electrical load **110** may be used to produce enhanced results. Where the electrically conductive probe **105** is an array (e.g., the array **105***d* in **FIG. 2D**), each element of the array can include an ionization source **305** on the end thereof. The ionization source **305** contains a low level, radioactive source of alpha or beta particles encapsulated in a suitable material. Suitable alpha emitters include, but are not limited to, isotopes of Polonium and Americium (Am). Suitable beta emitters include, but are not limited to, Tritium. Suitable encapsulating materials include, but are not limited to, glass compositions such as silicate, borosilicate, aluminasilicate, and borate. In some embodiments, the point **150** can be doped with an alpha emitter or a beta emitter during manufacture.

[**0037**] Suitable alpha and beta emitters are commercially available. For instance, suitable alpha emitters are sold under the mark RadSPHERES™ by:

MO-SCI Corporation

4000 Enterprise Drive, P.O. Box 2

Rolla, Mo. 65402-0002

573-364-2338 (ph)

573-364-9589(fax)

[**0038**] Additional information is available on the World Wide Web at <http://www.thomasregister.com/olc/mo-sci-corp/radsph.htm>. The RadSPHERES™ alpha emitters are glass microspheres of encapsulated low-level radioactive materials. Alternatively, the low-level radioactive material may be encapsulated in a bar-shaped material. However, other commercially available alpha emitters and beta emitters may also be employed.

[**0039**] Some embodiments successfully employ further ionization efficiency than that provided by the ionization source **305** in **FIG. 3**. One such embodiment **400** is conceptually illustrated in **FIG. 4**. In **FIG. 4, a** second ionization source **405** is on or near the electrical load **110** on the end thereof opposite the first point **140** where the electrically conductive probe **105** is electrically connected to the electrical load **110**. The second ionization source **405** may, like the first ionization source **305**, be any suitable alpha or beta particle emitter. In the illustrated embodiments, the first and second ionization sources **305**, **405** are of the same construction and materials, but this is not necessary to the practice of the invention.

[**0040**] Turning now to **FIG.** 5A and **FIG.** 5B, in operation, the relative movement between the electrically conductive probe **105** and the ambient atmosphere, generally indicated by the arrows **500**, ionizes the air streaming past the electrically conductive probe **105**. Hence, the potential created between the first point **140** and the second point **150** on the electrically conductive probes **105**. Each ionization source **305** creates an ionization region **505**, which is a volume of air ionized by the ionization source **305** without having to stream past the electrically conductive probe **105**. The increase in the volume of ionized air increases the efficiency of the coupling to the electrostatic field gradient in the vicinity of the ionization source **305**, which includes at least a portion of the electrically conductive probe **105**. Thus, as the ionization sources **305** increase the volume of ionized air, they increase the efficiency of the coupling to the electrostatic field gradient.

[**0041**] Note that the embodiments described above contemplate that the ion powered platforms **100, 300, 400,** move relative to Earth's atmosphere. However, this is not necessary to the practice of the invention. The same effect can be achieved by placing a stationary ion powered platform in a location with air movement. Consider, for instance, the ion powered platform **600** shown in **FIG. 6A**. The ion powered platform **600** is a sensor, but is stationary. The ion powered platform **600** includes an electrically conductive probe **605** that is an array. The elements of the array **605** are rigid, and each has an ionization source **305** electrically connected to the end thereof as was described above. The ion powered platform **600** also includes an ionization source **405** on the other side of the electrical load **110**, which is a capacitor in the illustrated embodiment. **FIG. 6B** conceptually illustrates the electrical circuit of the ion powered platform **600**, first shown in **FIG. 6**A, which includes a transformer **620**. The ion powered platform **600** is then placed in an area expected to consistently experience high winds, represented by the arrow **615**. If the winds are high and consistent enough, the fuse capacitor (i.e., the electrical load **110**) will charge and the sensor (i.e., the ion powered platform **600**) may then be activated.

[**0042**] Yet another alternative embodiment **700** is illustrated in **FIG. 7**A and **FIG. 7B**. The embodiment **700** is part of a propeller-driven propulsion system for a flying vehicle not otherwise shown. The propeller **705** includes three blades **710**. The number of blades **710** is immaterial to the practice of the invention. Each blade **710** is doped at the distal end **715** thereof to produce a primary ionization source **305**. Each primary ionization source **305** generates an ionization region **505** as described above relative to the embodiment **500** shown in **FIG. 5**. The embodiment **700** also includes a secondary ionization source **405**. The electrical load **110** in this embodiment is a motor for driving the propeller **705**. The motor may be, for example, a surface acoustic wave linear motor, an ultrasonic motor, or an electrostatic motor, depending on the implementation.

[**0043**] The embodiment **700** is launched from another flying vehicle, and so is moving relative to the atmosphere. As is best shown in **FIG. 7**B, the atmosphere streams past the primary ionization sources **305** on the distal ends **715** of the blades **710** and through the ionization regions **505**, as represented by the arrows **720**. The ionized atmosphere completes an electrical circuit between the first point **140** (i.e., the electrical ground) on the ring **725** and the second points **150** on the distal ends **715**. Thus, the electrically conductive probe **105** in this embodiment is implemented in an ionized fluid medium as opposed to an electrically conductive solid.

[**0044**] Thus, the invention includes, in another aspect, a method **800**, illustrated in **FIG. 8**, for powering an electrical load (e.g., the electrical load **110** in **FIG. 1**) on a ion powered platform (e.g., the ion powered platforms **100**, **300**, **400**, **600**, in **FIG. 1**, **FIG. 3**, **FIG. 4**, and **FIG. 6**A, respectively) with ions. The method **800** begins by extending a first point on an electrically conductive probe at least a predetermined vertical distance from a second point on the electrically conductive probe at which the electrically conductive probe is electrically connected to the electrical load (at **810**). This extension may occur during fabrication, between fabrication and deployment, or after deployment. Next, the method **800** initiates relative movement between the ambient atmosphere and the electrically conductive probe (at **820**). Note that the movement is relative. As is apparent from the discussion above, the relative to some fixed point, the ion powered platform may move through the atmosphere, the atmosphere may move over the ion powered platform, or both the ion powered platform and atmosphere may move. Finally, the method **800** supplies the energy generated by the electrical potential created by initiating the relative movement to the electrical load (at **830**).

[**0045**] This concludes the detailed description. The particular embodiments disclosed above are illustrative only, as the invention may be modified and practiced in different but equivalent manners apparent to those skilled in the art having the benefit of the teachings herein. Furthermore, no limitations are intended to the details of construction or design herein shown, other than as described in the claims below. It is therefore evident that the particular embodiments disclosed above may be altered or modified and all such variations are considered within the scope and spirit of the invention. Accordingly, the protection sought herein is as set forth in the claims below.

What is claimed:

1. An ion powered platform, comprising:

a platform body;

an electrical load carried by the platform body; and

an electrically conductive probe electrically connected to the electrical load at a first point thereon and adapted to generate electrical energy from an ambient electrostatic field gradient, the electrically conductive probe extending from the electrical load such that a second point thereon is vertically displaced from the first point and on the opposite connection of the load.

2. The ion powered platform of claim 1, further comprising an ionization source electrically coupled to the second end of the probe.

3. The ion powered platform of claim 2, wherein the ionization source comprises one of an alpha-particle emitter and a beta-particle emitter.

4. The ion powered platform of claim 3, wherein the alpha-particle emitter includes one of Polonium and Americium.

5. The ion powered platform of claim 4, wherein the Polonium or Americium is encapsulated in one of silicate, borosilicate, aluminasilicate, and borate.

6. The ion powered platform of claim 3, wherein the beta-particle emitter includes Tritium.

7. The ion powered platform of claim 2, further comprising a second ionization source affixed to the electrical load at a third point on the electrical load distal from the first point.

8. The ion powered platform of claim 7, wherein the second ionization source comprises one of an alpha-particle emitter and a beta-particle emitter.

9. The ion powered platform of claim 8, wherein the alpha-particle emitter includes one of Polonium and Americium.

10. The ion powered platform of claim 9, wherein the Polonium or Americium is encapsulated in one of silicate, borosilicate, aluminasilicate, and borate.

11. The ion powered platform of claim 8, wherein the beta-particle emitter includes Tritium.

12. The ion powered platform of claim 1, wherein the electrically conductive probe comprises one of a fiber, a ribbon, a rod, a ring, and a sheet.

13. The ion powered platform of claim 12, wherein the fiber comprises an electrically conductive carbon filament.

14. The ion powered platform of claim 13, wherein at least one of the ribbon, the rod, the ring, and the sheet comprises a plurality of electrically conductive carbon filaments, a metallized glass, a metal coating, or a metallized polymer.

15. The ion powered platform of claim 1, wherein the electrically conductive probe comprises

a first ionization source;

a second ionization source; and

an ionized fluid medium between the first and second ionization sources.

16. The ion powered platform of claim 15, wherein at least one of first and second ionization sources comprises one of an alpha-particle emitter and a beta-particle emitter.

17. The ion powered platform of claim 16, wherein the alpha-particle emitter includes one of Polonium and Americium.

18. The ion powered platform of claim 17, wherein the Polonium or Americium is encapsulated in one of silicate, borosilicate, aluminasilicate, and borate.

19. The ion powered platform of claim 16, wherein the beta-particle emitter includes Tritium.

20. An ion powered platform, comprising:

a platform body;

an electrical load carried by the platform body; and

means for generating electrical energy from an ambient electrostatic field gradient.

21. The ion powered platform of claim 20, further comprising a first means for ionizing a region of air, the ionizing means being electrically coupled to the generating means.

22. The ion powered platform of claim 21, wherein the ionizing means comprises one of means for emitting alpha-particles and means for emitting beta-particles.

23. The ion powered platform of claim 21, further comprising second means for ionizing a region of air electrically coupled to the generating means.

24. The ion powered platform of claim 20, wherein the generating means comprises one of a fiber, a ribbon, a rod, a ring, and a sheet.

25. The ion powered platform of claim 20, wherein the generating means comprises:

first means for ionizing a region of air;

second means for ionizing a region of air; and

an ionized fluid medium between the first and second ionizing means.

26. A method for powering an electrical load on an ion powered platform with ions, comprising:

positioning a first point on an electrically conductive probe at least a predetermined vertical distance from a second point on the electrically conductive probe at which the electrically conductive probe is electrically connected to the electrical load;

initiating relative movement between an ambient atmosphere and the electrically conductive probe; and

supplying energy generated by an electrical potential created by initiating the relative movement to the electrical load.

27. The method of claim 26, further comprising providing an ionization source as the first point.

28. The method of claim 27, further comprising providing a second ionization source on the side of the electrical load opposite the second point.

29. The method of claim 26, further comprising providing an ionization source on the side of the electrical load opposite the second point.

30. The method of claim 26, wherein extending the first point on the electrically conductive probe at least the predetermined vertical distance from the second point includes extending on deployment of the ion powered platform.

31. The method of claim 26, wherein extending the first point on the electrically conductive probe at least the predetermined vertical distance from the second point includes extending on manufacture of the ion powered platform.

32. The method of claim 26, wherein initiating the relative movement includes placing the ion powered platform in motion.

33. The method of claim 26, wherein initiating the relative movement includes deploying the ion powered platform in expectation of a desirable wind pattern.

(57) **ABSTRACT**

This invention relates to a spacecraft which generates its own magnetic moment and magnetic field gradient in order to produce lift on the hull. The magnetic moment is generated by a large area solenoid located in the hull. A toroidal core wrapped with electrical bobbins at intervals along said core produces a traveling magnetic wave along its surface. This magnetic wave creates a spacetime curvature, similar to a tilted plate, which causes the formation of a magnetic field gradient. Power is not critical because the system uses a magnetic vortex wormhole generator to lower the speed of light in order to efficiently create highly relativistic fields due to Lorentz transformation.
